SECTION 1

Introduction

1.0.1 CH2M HILL is performing a Remedial Investigation and Feasibility Study (RI/FS) focused on Areas 1, 6, 6A, 6B, 9, 10, 11, 12, 13, 16, 18D, 19, and the Dredge Spoils Area (DSA) at the Former Raritan Arsenal in Edison, New Jersey. This document was prepared for the U.S. Army Engineering and Support Center, Huntsville, Alabama (CEHNC) as part of Contract Number W912DY-09-D-0060, Task Order 0003, and the U.S. Army Corps of Engineers (USACE) New York and New England Districts to document the initial phase of the investigation to locate and characterize munitions and explosives of concern (MEC) and material potentially presenting an explosive hazard (MPPEH) in the subsurface at the Former Raritan Arsenal.

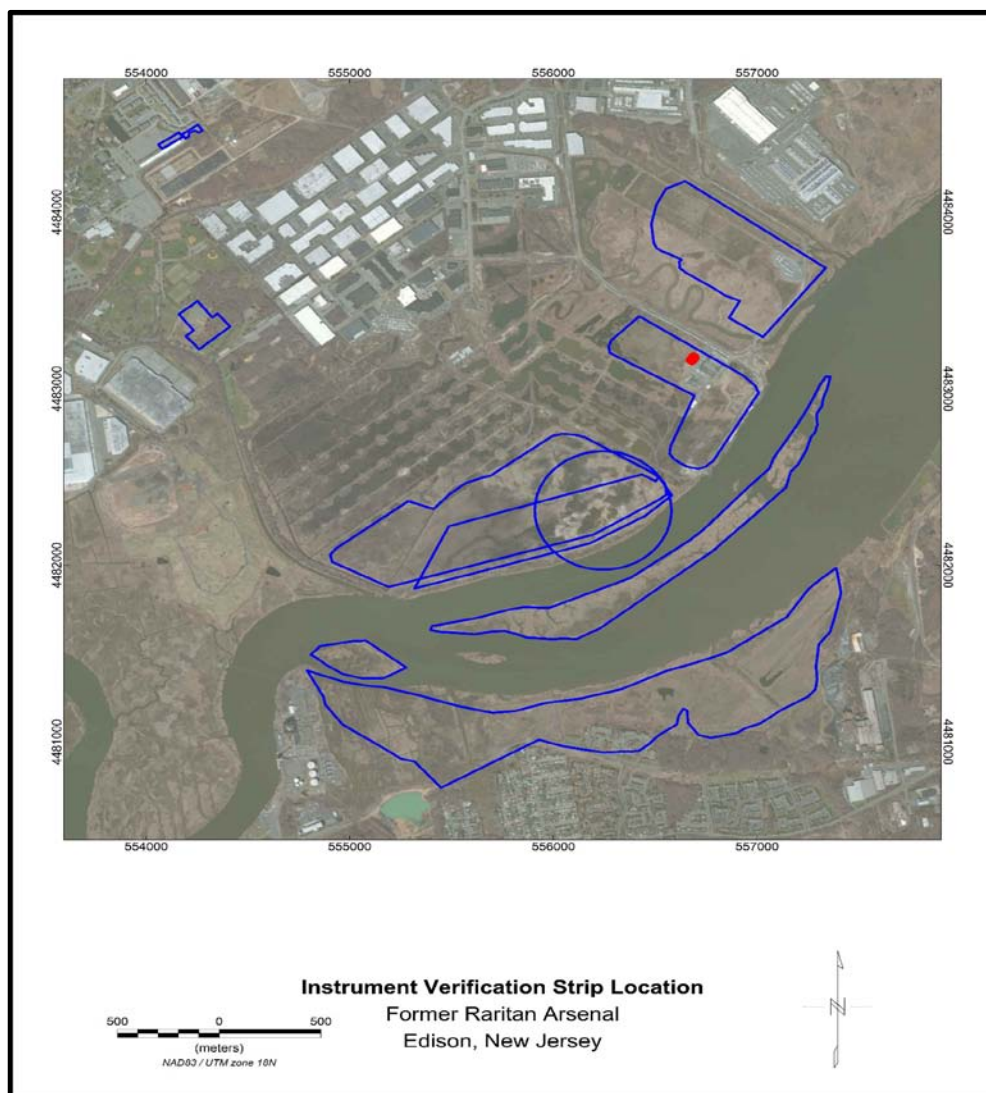

1.0.2 CH2M HILL employed a two-stage physics-based verification process in which signal strength and sensor performance were demonstrated initially by static and dynamic tests on a test strip and throughout the survey with a blind seeding program. The initial phase involved verification of both the single-coil person-portable Geonics Ltd. EM61-MK2 digital geophysical mapping (DGM) system and the three-coil vehicular towed array EM61-MK2 DGM system using an instrument verification strip (IVS). The second phase involved the burial of small industry standard objects (ISOs) within the investigation areas to demonstrate the continued effectiveness of the system and of the survey methodology. The results of the blind seeding program will be discussed in the final RI Report. The IVS process followed the Geophysical System Verification (GSV) Plan presented in Appendix F of the Remedial Investigation Work Plan.

SECTION 2

Instrument Verification Strip Location and Setup

2.0.1 On December 3, 2013, the CH2M HILL Quality Control (QC) Geophysicist and Unexploded Ordnance Quality Control Manager (UXOQCM) established an IVS at the location in Dredge Spoils Area (DSA) #2 marked in red on [Figure 2-1](#). A Trimble R8 Global Navigation Satellite System (GNSS) receiver was utilized for data positioning¹, with a Trimble R8 base station on the “A-701” control point, which was established by Vargo Associates, the project licensed New Jersey professional land surveyor (PLS). The real-time kinematic (RTK) global positioning system (GPS) was tested at a previously-installed survey stake (“TDSA2-6B”) prior to recording the IVS coordinates and found to be accurate within 1 centimeter (cm).

FIGURE 2-1
IVS Location

¹ All coordinates reported in this document and in the IVS data are accurate to the North American Datum of 1983 (NAD83) Universal Transverse Mercator (UTM) Zone 18 North (meters) coordinate system.

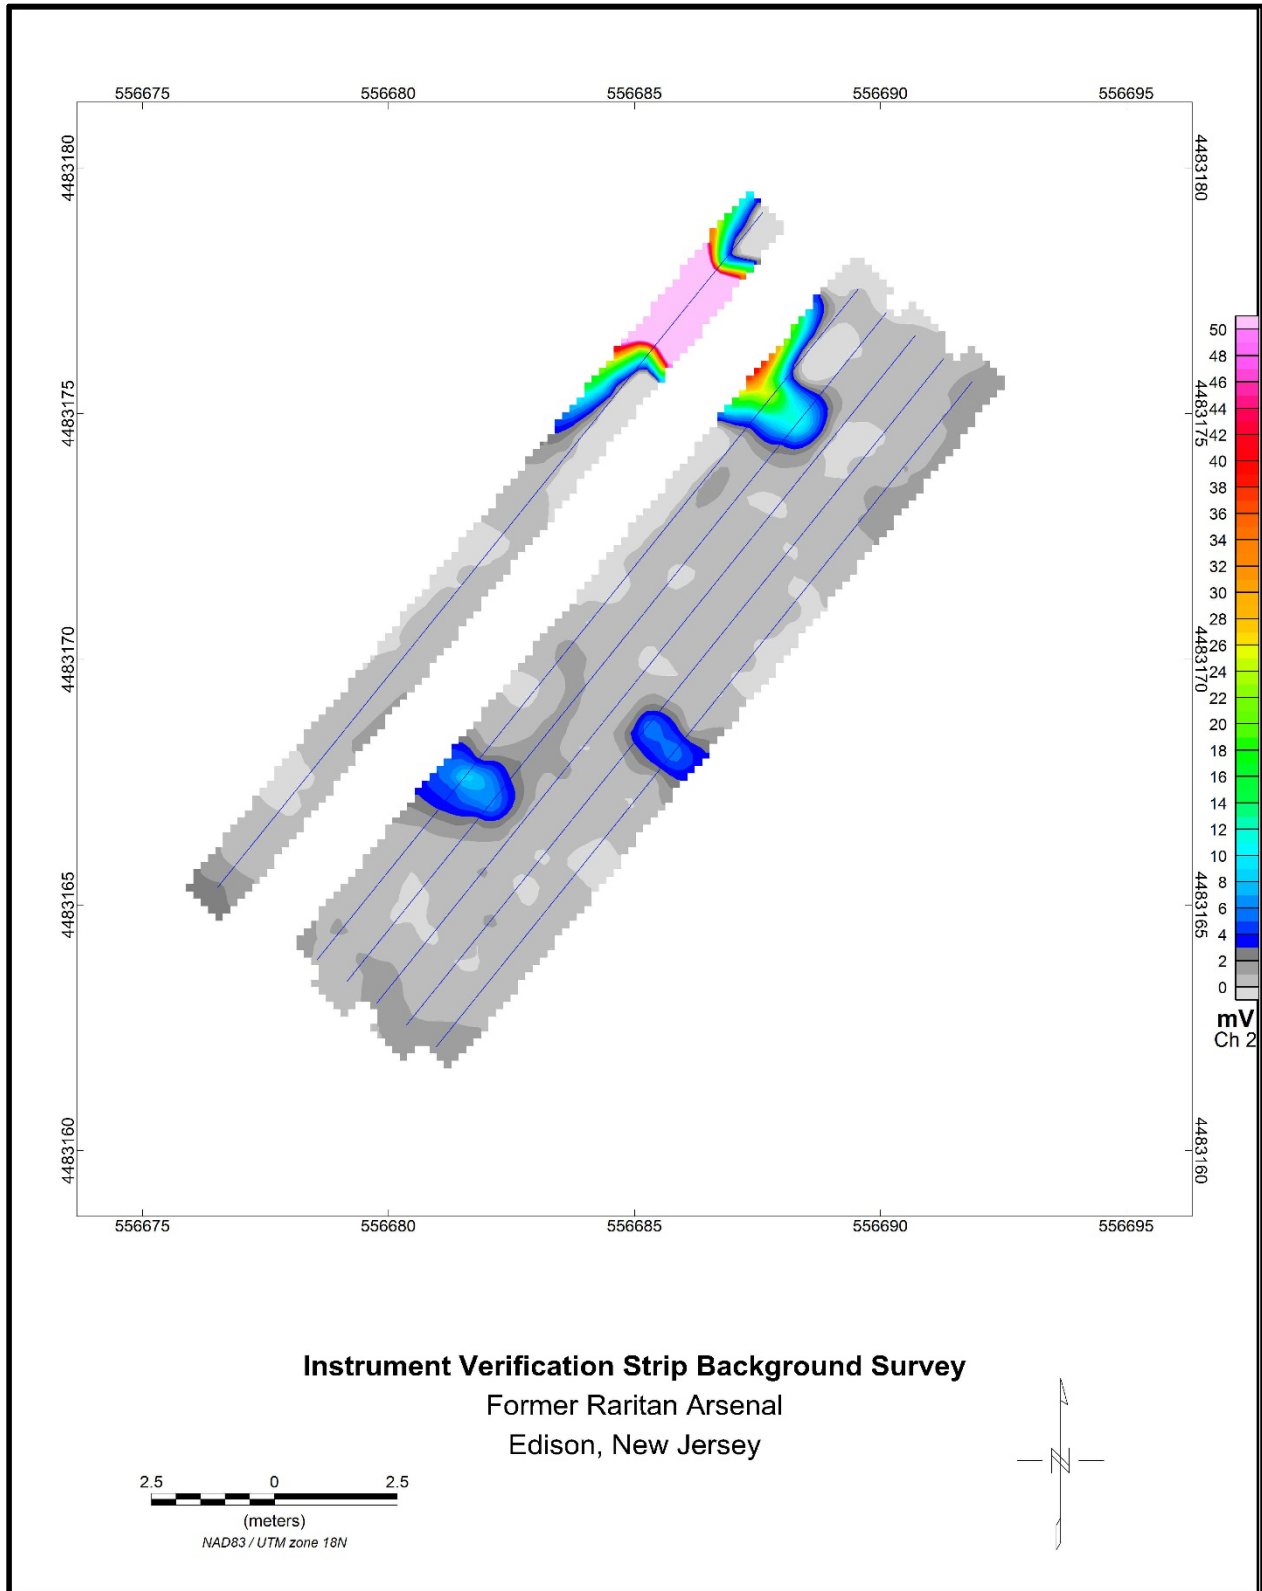

2.0.2 Prior to each IVS geophysical survey, daily QC tests were performed with the EM61-MK2 systems, as described in the Remedial Investigation Work Plan. The following daily functional tests were conducted:

- **Equipment Warm-up.** The EM61-MK2 systems were allowed to warm up for more than 10 minutes prior to beginning QC tests and data collection.
- **Record Sensor Positions.** The R8 GPS rover antenna was positioned over a known point ("TDSA2-6B"), and its location was recorded to demonstrate the system positioning accuracy.
- **Personnel Test.** To verify that all personnel operating or working within close proximity to the survey platforms were free of magnetic and/or conductive material that could potentially affect the survey data, the EM61-MK2 systems were checked for any response to the personnel operating the systems. Data was recorded continuously for the duration of the test as each system operator approached the instrument receiving coils to identify objects on the operator's person that could affect the survey data. The response was observed in the field for immediate corrective action, and transmitted back to the data processor, where it was analyzed and checked for spikes in the data that could result in false anomalies.
- **Cable Shake Test.** To ensure that movement of cables on the survey equipment did not introduce significant noise, and that there were no loose connections or shorts in cables that could introduce noise spikes, data were continuously recorded in a static location as each system cable and connection was shaken. The response was observed in the field for immediate corrective action and transmitted back to the data processor, where it was analyzed and checked for spikes in the data that could result in false anomalies.
- **Static Background and Static Spike.** The static test was performed by positioning the EM61-MK2 systems in an area free of metallic contacts and collecting data for a 3-minute period. During this time, the instruments were held in a fixed position for 1 minute to measure the background response, then for 1 minute with a small ISO spike at a precisely measured orientation and distance (43 cm) from each sensor coil, and finally for 1 minute without the ISO to again measure the system response to background conditions. The purpose of the static test was to determine whether unusual levels of instrument or ambient noise existed.

2.0.3 As part of the IVS survey, the repeat data functional test was also conducted. This test was performed to verify repeatability of the data after the initial survey over the IVS by resurveying the line over the seeded IVS items. The initial repeat data test was conducted at the IVS, where line paths are well constrained, because repeatability of the survey data is generally high. Due to the intrinsic difficulty of following the exact path for collecting repeat data, however, especially under field survey conditions, this test is a qualitative comparison as opposed to a quantitative comparison.

2.0.4 After the instrument QC tests were performed, the single-coil person portable EM61-MK2 system was used to conduct a background survey of the general area identified by CH2M HILL as a potential location for the IVS. The location was not entirely free from geophysical anomalies, however, there was sufficient space between existing anomalies for the placement of the IVS seed items. The background survey over the selected plot is shown on [Figure 2-2](#).

FIGURE 2-2
IVS Background Survey

2.0.5 The CH2M HILL Quality Control Geophysicist buried six IVS seed items as specified in the GSV Plan. All seed items were small schedule 40 ISOs, as shown on [Figure 2-3](#). The seed item locations were confirmed to be clear of geophysical anomalies by the CH2M HILL UXOQCM prior to emplacement. After placement of the items, the locations were recorded using the Trimble R8 RTK GPS. The locations, depths and orientations of the IVS seed items are shown in [Table 2-1](#). An as-built map of the IVS is shown on [Figure 2-4](#), and a photograph of the IVS is presented on [Figure 2-5](#).

FIGURE 2-3

SECTION 3

Instrument Verification Strip Surveys and Results

3.1 Instrument Verification Strip Surveys

3.1.1 Initial IVS surveys were conducted with three separate EM61-MK2 systems for use in the Former Raritan Arsenal DGM surveys. The single-coil person-portable systems were validated with a standard 5-line IVS survey as described in the GSV Plan. The primary line in the person-portable IVS surveys passed directly over 2 buried seed items (ISO 2 and ISO 5). The triple-coil towed array system was validated with a survey over the IVS in which each coil in the array passed directly over 2 buried seed items. Abbreviated IVS surveys were conducted with each EM61-MK2 system on a twice-daily basis when that system was in use as a continuing verification of the dynamic performance of the system.

3.1.2 The following EM61-MK2 systems were validated at the IVS:

- a single-coil person-portable system utilizing fiducial positioning methods
- an RTK-GPS-positioned triple-coil towed array system towed behind an Argo utility task vehicle
- a single-coil person-portable system with RTK-GPS positioning

3.1.3 The single-coil person-portable system utilizing fiducial positioning methods and the triple-coil towed array system were both validated on December 3, 2013. The IVS survey with the single-coil person-portable system was conducted on December 13, 2013. The triple-coil system towed behind the Argo utility task vehicle is shown on [Figure 3-1](#) conducting the IVS survey.

FIGURE 3-1
Triple-Coil Towed-Array EM61-MK2 IVS Survey

3.1.4 Responses from the IVS seeds may vary from the predicted values because of variables that intrinsically inject error into the measurement, including the following:

- **Depth Measurement:** if terrain is not completely flat around excavated holes, an average of the ground level must be determined in the field, potentially resulting in differences of up to several centimeters
- **Instrument Path:** while the instrument operator attempts to maintain a central path over the seeded items, slight variation to either side can impact the measured response
- **Measurement Location:** because the instrument records are at set measurement intervals, the actual measured response may not be directly over the seed item
- **Instrument Bounce:** unless terrain is absolutely flat around the excavation, the motion of the DGM system may cause the transmit/receive coil to vary in height above the ground surface by several centimeters from the height used to predict the response curve

3.1.5 Because there is limited ability to control these error variables, the primary quality measure of the instrument response is the static test with the ISO at a strictly controlled distance from the transmit/receive coil. The dynamic survey over the IVS seeds is a secondary measure and can be used to demonstrate kinematic (in motion) detection of the ISOs, demonstrate appropriate falloff of response from deeper items, measure representative background response, and demonstrate positioning system accuracy under kinematic conditions.

3.1.6 All IVS data has been provided to the USACE Geophysicist for review, and will also be delivered on DVD with the final Digital Geophysical Mapping Report.

3.2 Results

3.2.1 Single-Coil Person Portable EM61-MK2 with Fiducial Positioning

3.2.1.1 The IVS was surveyed on December 3, 2013, using the single-coil person-portable EM61-MK2 system with fiducial positioning. The survey results are shown on [Figure 3-2](#) and described in the following section. The quantitative daily static test results are shown on [Figure 3-3](#).

FIGURE 3-2
Single-Coil Person Portable EM61-MK2 (Fiducial Positioning) IVS Survey Results

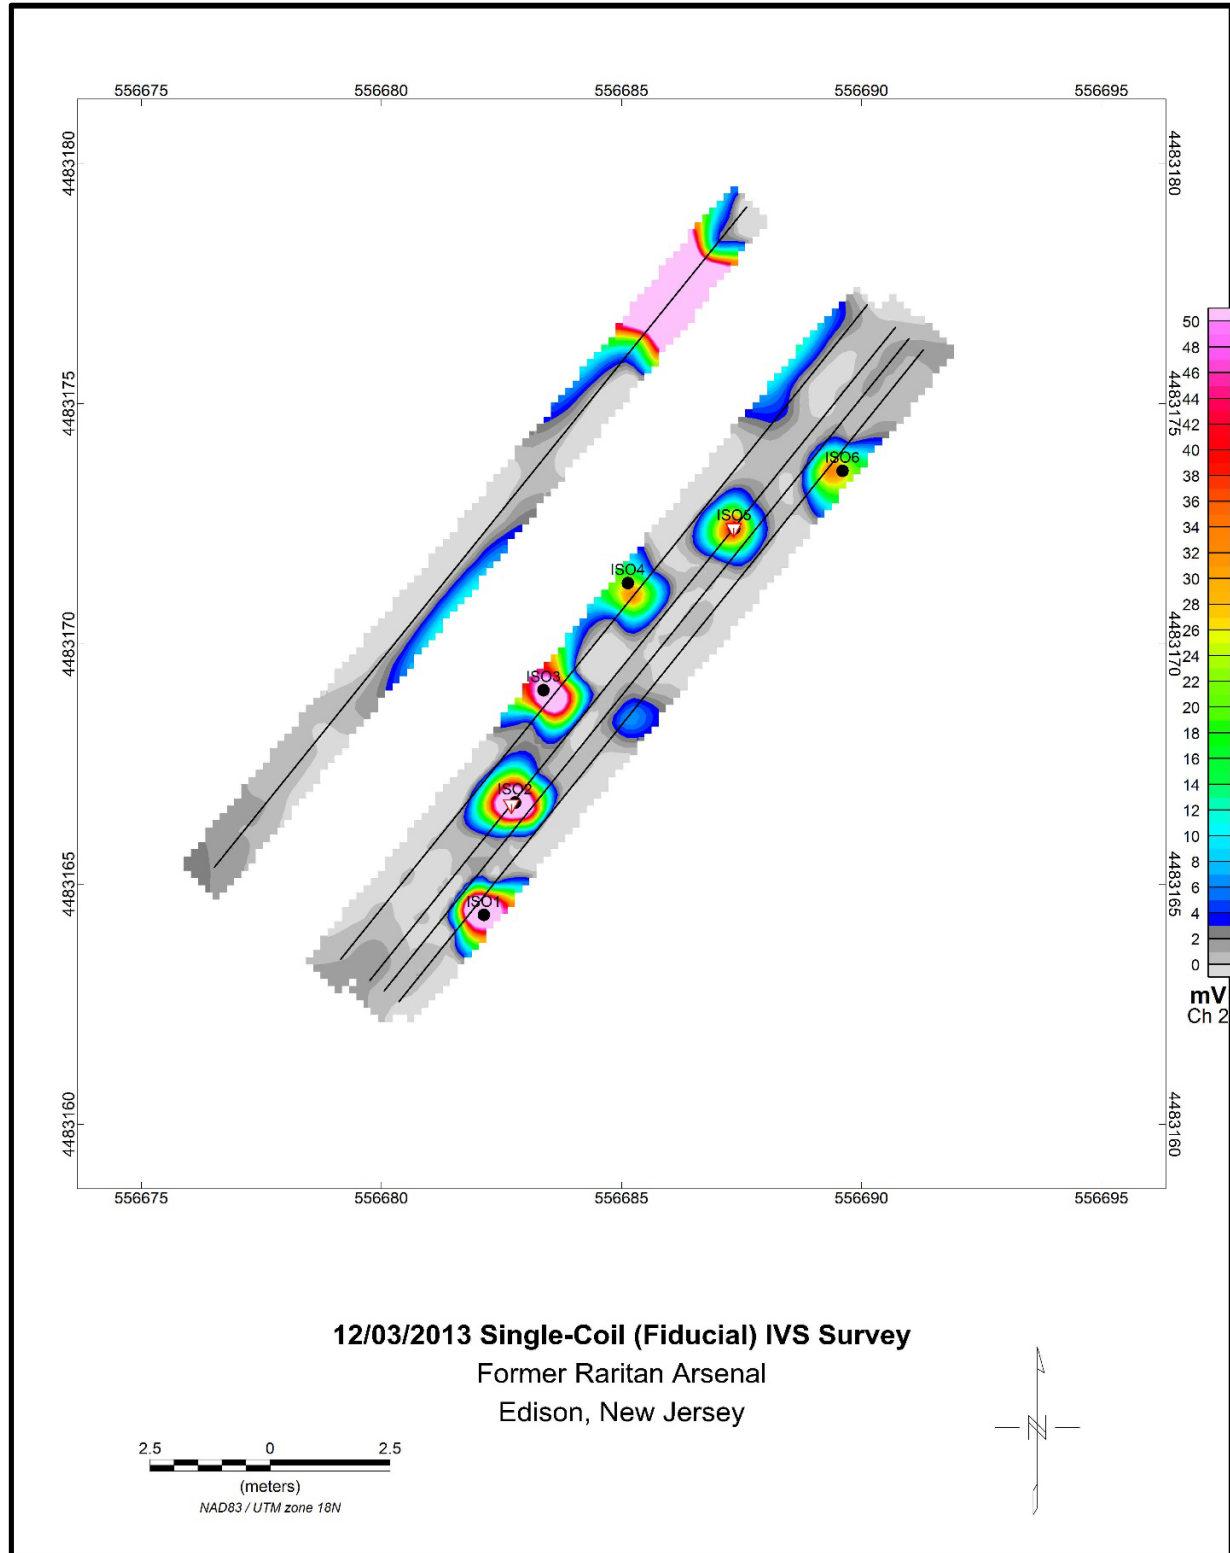

FIGURE 3-3

Person Portable (Fiducial Positioning) Static Test Results Compared to Predicted Small Horizontal ISO Response²

Notes: A small industry standard object mounted horizontally 43cm from the sensor coil is used as the test spike item.

3.2.1.2. The objective of repeatable (within 25%) daily IVS anomaly characteristics is difficult to quantify at the initial IVS survey without a standard set by previous DGM surveys over the IVS items. After several days of hindsight, however, the response values from the initial person-portable (with fiducial positioning) IVS survey can be compared to the average response of each IVS items, as shown in [Table 3-1](#).

TABLE 3-1

Person-Portable (Fiducial Positioning) IVS Seed Item Response Characteristics

IVS Item	Average Response (mV) ¹	Initial IVS Response (mV)	Difference from Average
ISO 2	86.8	91.2	5.1%
ISO 5	41.5	43.3	4.3%

Notes:¹ Average response of each IVS seed item over the course of the first week of person-portable IVS surveys

FIGURE 3-7

Person Portable (RTK-GPS Positioning) Static Test Results Compared to Predicted Small Horizontal ISO Response

Notes: A small industry standard object mounted horizontally 43cm from the sensor coil is used as the test spike item.

3.2.3.2 The response values from the initial person-portable (with RTK-GPS positioning) IVS survey are compared to the average response of each IVS item previously surveyed with the person-portable system, as shown in [Table 3-3](#).

TABLE 3-3

Person Portable (RTK-GPS Positioning) IVS Seed Item Response Characteristics

IVS Item	Average Response (mV) ¹	Initial IVS Response (mV)	Difference from Average
ISO 2	85.9	84.6	1.5%
ISO 5	39.9	39.2	1.8%

Notes:¹ Average response of each IVS seed item over the course of the first week of person-portable IVS surveys

SECTION 4

Quality Control and Measurement Quality objectives

4.0.1 All QC tests were performed as specified in the project work plan. No discrepancies were noted, and all data have been provided to the USACE Geophysicist. The measurement quality objects (MQOs), measurement performance criteria (MPC), and test methods established for the IVS are summarized in [Table 4-1](#) along with the MQO results.

TABLE 4-1
Measurement Quality Objectives and IVS Results

MQO	Measurement Performance Criteria	Test Method
General System Function		
DGM Systems Positioning. Accurate positioning information is provided to DGM system.	The positional error of the system at known locations will not exceed 10 cm (4 inches) when individual MEC items need to be located. When the objective of the survey is to delineate the extent of a trench (e.g. Area 18D) the positional error of the system at known locations will not exceed 1.5m (4.9 ft).	Results of QC Test #2 were evaluated for compliance. All positioning system test met the MPC.
Repeatability. Repeatable and accurate data are being obtained from DGM system.	Response to ISO will not vary more than ± 20 percent from known response for specific distance from sensors in static tests conducted at the beginning and end of each survey day. Response of repeat line is comparable to original line data (qualitative determination).	Results of QC Test #5 were evaluated quantitatively and compared to published response values for compliance. All static test results met the MPC.
DGM Surveys		
Downline Data Density. Downline data density is sufficient to detect MEC items.	Over 98 percent of possible sensor readings are captured along a survey transect with a spacing of no greater than 0.2 m (0.7 ft.) between points. A data gap greater than 0.6 m (2 ft.) will not meet the MQO.	Results of DGM surveys were quantitatively evaluated for compliance. All data was in compliance with the downline data density MQO.
Survey Coverage. Maintain appropriate line spacing to provide 100% coverage of accessible portions of the survey area.	Greater than 90% survey coverage at the project design line spacing of 0.75 m for EM61-MK2 comprehensive (full coverage) surveys. Lane spacing for transect surveys will not vary greater than 20% from intended spacing unless vegetation, terrain or other obstructions cause the separation.	Results of DGM surveys were quantitatively evaluated for compliance. All data was in compliance with the survey coverage MQO.
Dynamic Detection Repeatability.	Comprehensive terrestrial surveys: Repeat data is comparable to original data. The number of anomalies on the repeat segment will be within 20% of the original data. Transect surveys: IVS anomaly characteristics (peak response and size) are repeatable within 25%.	Comprehensive surveys: At least 2% of the survey area was repeated and evaluated for compliance. The IVS repeat data was comparable to the original data. Transect surveys: Daily IVS surveys will be evaluated for compliance.

SECTION 5

Conclusions

5.0.1 CH2M HILL constructed an IVS and performed IVS surveys to verify the functionality of three DGM systems to be used for surveys at the Former Raritan Arsenal. The systems were verified as functioning within industry standards and meeting project MQOs.

5.0.2 Based on the variations in EM61-MK2 response seen in the background IVS survey, on the known instrument responses to various munitions items, and to include anomalies potentially related to munitions components, as well as those representing fully intact munitions items expected at the site, a threshold of 4 millivolts in the second EM61-MK2 time gate was selected for anomaly identification. The following approach is planned:

- Utilize a baseline anomaly selection threshold of 4 mV on channel 2 of the EM61-MK2 provided each anomaly has good decay and profile shape³, removing noted surface metal items
- Re-evaluate and adjust selection criteria if background noise on any particular transect or area is higher than that observed in the IVS

³ While there are no absolute measures for good decay and profile shape, and the experience of the data processor is important in determining this, the general measures are that the amplitude of each subsequent channel (Channels 1 through 4) is less than the previous channel and the response falls off in a parabolic shape to either side of the anomaly.

ATTACHMENTS: Anomalies Selected for Intrusive Investigation

Introduction

This technical memorandum presents the digital geophysical mapping (DGM) survey data and results of the statistical analysis to determine the number and locations of the DGM anomalies to be intrusively investigated at Dredge Spoils Area (DSA) 1 as part of the Remedial Investigation at the Former Raritan Arsenal in Edison, New Jersey. CH2M HILL prepared this document under the Defense Environmental Restoration Program – Formerly Used Defense Sites program, for submittal to the U.S. Army Engineering and Support Center, Huntsville, Alabama, as part of Contract Number W912DY-09-D-0060, Task Order 003, and the U.S Army Corp of Engineers – New York and New England Districts.

The objective of the DGM was to characterize the extent of geophysical anomalies that may be indicative of munitions and explosives of concern (MEC) and material potentially presenting an explosive hazard (MPPPEH) at the site. The majority of the DGM survey was conducted along 3-meter wide transects nominally spaced at 80 meter intervals across the site. A small portion of the site was surveyed along 1-meter wide transects nominally spaced at 3 meter intervals to provide more detailed coverage in an area of potential pits to the southwest of the shipping facility parking lot.

The fieldwork was conducted in accordance with the *Remedial Investigation/Feasibility Study Work Plan for the Former Raritan Arsenal, Edison, New Jersey* (herein referred to as the Work Plan; CH2M HILL, 2013). Background information, site history, and the conceptual site model are also presented in the Work Plan.

Digital Geophysical Mapping

The DGM survey at DSA 1 was conducted on December 11 and December 12, 2013. A detailed description of all activities in support of the DGM survey will be presented in a Remedial Investigation report to be prepared after the anomaly intrusive investigation. DGM across the majority of the site was conducted using a vehicular towed array system consisting of 3 EM61-MK2 time domain electromagnetic induction detector coils mounted side by side and towed behind an ARGO utility task vehicle along transects nominally spaced at 80 meter intervals. DGM in the potential pit area was conducted using a single person-portable EM61-MK2 along transects nominally spaced at 3 meter intervals. Positioning was accomplished using a real-time kinematic global positioning system.

The eastern end of Transect 3 was shifted to the south to avoid collecting DGM data over railroad tracks. Data could not be collected over approximately 100 meters near the eastern end of Transect 6 due to a large berm that

did not allow the safe passage of the DGM system or over a 15-meter section in the center of Transect 6 where a canal crossed the survey path (Figure 1).

The geophysical anomaly identification approach is described in the Work Plan. To include anomalies potentially related to munitions components, as well as those representing fully intact munitions items expected at the site, a threshold of 3 millivolts in the second EM61-MK2 time gate was selected for anomaly identification. A total of 441 point-source anomalies were identified along the DGM transects and are depicted on Figure 1. Two identified anomalies were related to quality control (QC) seed items, with 439 anomalies with unknown metallic sources that could potentially be MEC or MPPEH in the subsurface.

The geostatistical density mapping tool in Visual Sample Plan was utilized to extrapolate the anomaly density across DSA 1 based on the locations of the DGM transects and the anomalies identified along those transects. The results of the density mapping are shown on Figure 2. In general, anomaly density is low across the site, with the exception of the area surrounding the shipping facility parking lot and railroad tracks, where higher anomaly concentrations are observed, some of which may be related to underground utilities. Smaller pockets of higher anomaly density are scattered throughout the site. The random sampling approach described below draws a statistically representative selection of anomalies from both higher density and lower density areas. The distribution and density of anomalies will be considered, along with the intrusive investigation results, in the analysis of the nature and extent of MEC contamination at DSA 1.
