Subject: Transmittal of Final Report for Geophysical Investigation
Sylvania Corning FUSRAP Site – Hicksville, New York
GeoView Project Number 3376

Dear Mr. Florentino,

GeoView, Inc. (GeoView) is pleased to submit the final report that summarizes and presents the results of the geophysical investigation performed at the above referenced site. Time domain electromagnetics and ground penetrating radar were used to help determine the presence of buried drums or underground storage tanks and to identify the location of historical leach pools, drains and drywells within the accessible areas of the project site. GeoView appreciates the opportunity to have assisted you on this project. If you have any questions or comments about the report, please contact us.

Sincerely,
GEOVIEW, INC.

Christopher Taylor, P.G.
Vice President

Michael J. Wightman, P.G.
President
Florida Professional Geologist Number 1423

1.0 Introduction

A geophysical investigation was conducted at the Sylvania Corning FUSRAP Site located in Hicksville, New York. The project site consisted of a 10.5-acre area partially abandoned industrial facility divided into three separate but contiguous properties located at 70, 100, and 140 Cantiague Rock Road. (Figures 1 and 3). Of concern was the presence or absence of any remaining buried drums or underground storage tanks beneath the site and to identify the location of several of the historical leach pools, drains and drywells.

The geophysical investigation was conducted using time domain electromagnetics (TDEM) and ground penetrating radar (GPR). Mr. Chris Taylor, P.G. and Mr. Chris Kibler performed the investigation over a 5-day period on September 11th-15th, 2006.

2.0 Site Description

The site was approximately 10.5 acres in size. A chain link fence bordered the site. Three main buildings, Building 70, Building 100, and Building 140, were located within the survey area. Ground cover across the majority of the site was asphalt. Reinforced concrete was present within the floors of the three buildings. At the time of the geophysical investigation, the majority of the site was clear and accessible to the investigation.

During previous site activities and investigations, 57 buried drums were encountered and removed during the 1986 expansion of Building 70; one underground storage tank was encountered and abandoned in-place during the soil boring activities in Building 100; and several underground storage tanks were encountered and removed during remedial excavation activities to the east of Buildings 140 and 100, and south of Building 100. In addition, one underground storage tank was removed to the west of Buildings 140 and 100.

3.0 Description of Geophysical Investigation

The TDEM survey was conducted with a Geonics, Ltd. Model EM-61 Buried Metal Detector (EM-61). A discussion of the limitations of the survey grid is provided in Appendix A1.1. The survey was conducted along parallel lines spaced 5 ft apart. The TDEM readings were collected every 0.62 ft along the transect lines. The locations of the TDEM survey are shown in Figures 1 and 3. A total of 47,708 data readings were collected. The TDEM data was then contoured using Surfer^{tm}, a computer-contouring program. A discussion of the TDEM method is provided in Appendix A1.2.

The lateral sensitivity of the TDEM equipment to surficial metallic debris is usually 3 ft or less. In such areas, it is not possible to discriminate which portion of

the instrument response is being caused by the surficial debris and which portion (if any) is being cause by buried metallic debris. Accordingly, it is usually not possible to determine if buried metallic debris is present within 3 ft of areas where surficial metallic debris is present. It is also not possible to determine the depth of debris burial in areas where the TDEM response is affected by the presence of surficial metallic debris.

The GPR survey was conducted along a series of perpendicular or parallel transects spaced 10 ft apart. The results of this survey are presented in Figures 2 and 4. Additional GPR transects were performed using a smaller GPR grid over the suspected locations of the eight historical leach pools, drains, and drywells and over the majority of the EM-61 anomalies.

On the exterior of the buildings, the GPR data was collected using a Mala radar system with a 500-megahertz antenna. A time range setting of 60 to 90 nano-seconds was used. This time range setting provided information to an estimated depth of 5 to 11 ft below land surface (bls). On the interior of the buildings, the GPR data was collected using a Mala radar system with 500-megahertz and 800-megahertz antennas. A time range setting of 15 to 70 nano-seconds was used. This time range setting provided information to an estimated depth of 3 to 4 ft below land surface (bls). The reinforced concrete slab limited the penetration of the GPR signal. A detailed description of the GPR technique and the methods employed for debris studies is provided in Appendix A1.3.

4.0 Survey Results

4.1 Exterior Areas

The results of the geophysical investigation are presented in Figures 1-4. A summary of the results is provided in Table 1. The EM-61 data indicates multiple areas of elevated responses throughout the survey area. The majority of these areas of elevated response are due to reinforced concrete pads (visible at ground surface), fencing, possible underground utilities, manholes/drains, or other known metallic structures. However, several of the areas of elevated response may be due to areas of buried debris or other structures. These areas are indicated on Figures 1 and 3 as EM-61 Anomalies 1-35. GPR data collected within several of the EM-61 anomalies indicated areas of small shallow debris and did not indicate the existence of underground storage tanks or buried drums within the EM-61 anomalies. However, in some areas, the depth of penetration of the GPR signal was limited and the EM-61 may be responding to features that are buried beyond the depth of penetration of the GPR signal. Multiple circular anomalies were identified between buildings 100 and 140. These circular anomalies are the locations of drainage

structures installed during previous site activities. The locations of these structures are shown on Figures 1 and 2.

The GPR data identified seven additional anomalies. These anomalies are shown as GPR Anomalies A-G on Figures 2 and 4. GPR anomalies A and E are characterized by downwarping of the GPR reflectors and an increase of penetration of the GPR signal. These two anomalies may be areas of previous excavation activity. GPR Anomalies B, C, and F are characterized by parabolic reflections at depths ranging from 3 to 4 ft bls. These anomalies my indicate areas of possible buried debris. GPR anomalies D and G correspond to the possible locations of former drain DRYH-C and the drain within Building 140, respectively.

Additional geophysical testing was performed with an 800 MHz antenna and a Subsite Utility Locator at each of the proposed locations of the sub-slab sampling locations to identify possible utilities or other obstructions. If a utility was identified proximate to a proposed sampling location, the location of the suspected utility was marked with lumber crayon and the sampling location was moved to a more suitable location.

A known underground storage tank was located north of the northwest corner of Building 70. The existence of the underground storage tank was confirmed by the geophysical survey and the location of this underground storage tank is shown on Figures 3 and 4. Examples of the GPR data showing GPR Anomalies A and F are provided in Appendix 1.

4.2 Interior Areas

Initial GPR tests were performed across the location of a known underground storage tank located within the southeast corner of the interior of Building 100. The testing was performed to determine whether significant GPR signal penetration could be achieved to meet the project objectives of identifying underground storage tanks inside of the buildings. The underground storage tank was at a depth of 6 to 6.5 ft bls. The GPR signal did not have sufficient depth of penetration and was therefore not able to resolve the underground storage tank. Additional testing was performed within of western portion of Building 70, the eastern portion of Building 100 and the central portion of Building 140. Several utilities were identified at a maximum depth of 3 to 3.5 ft bls. Based on these results, it was determined that the signal penetration depth of the GPR was insufficient to identify unknown underground storage tanks or buried drums inside of the buildings. Accordingly, the GPR survey was not conducted throughout the remainder of the interior of the buildings. A discussion of the limitations of the GPR technique in underground storage tank/buried debris studies is provided in Appendix 2.3.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
A	1,2	High	High	6-7	20x20	Downwarping of GPR reflector and associated increase in penetration of GPR signal. Possible area of previous excavation. Coincides with Anomaly 3.
B	1,2	Medium	Low	1-3	3x3	Single parabolic reflection only evident on one GPR transect. It is suspected that Anomaly B is small amounts of minor near surface debris.
C	1,2	Medium	Low	2-3	3x3	Anomaly comprised of multiple reflections, indicating multiple, smaller objects
D	3,4	High	Interference from metal fence	2-4	2x2	Single parabolic reflection. Anomaly D was located 5 ft to the northeast of the reported location of former drywell DRYH-C.
E	3,4	High	None	2-4	2x2	Apparent increase in depth of the GPR reflector and an increase in penetration of the GPR signal. May indicate an area of former excavation activity or a former pit.
F	3,4	High	High	2-4	8x20	GPR Anomaly is comprised of a single, strong parabolic reflection at a depth of 2-4 feet bls and several smaller, shallower parabolic reflections. Anomaly is located at the suspected termination of a utility identified by the EM-61 data.
G	1,2	Medium	Not Surveyed	2-4	3x3	Single parabolic reflection. Near reported location of DRH-A.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
1	1	Low	Medium	1-3	5x5	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
2	1	None	Medium	Unknown	7x10	Relatively large anomaly. Evident on 3 EM transects. May represent Former Leach Pool LPH-B.
3	1	High	High	6-7	5x10	Coincides with Anomaly A
4	1	Low	Medium	1-3	5x5	Possible area of buried debris. Evident of 4 parallel EM transect lines. Reinforced concrete barrier is located immediately north of Anomaly 4
5	1	None	High	Unknown	8x8	Larger EM-61 anomaly. No associated GPR anomaly. May be area of small, scattered near surface debris.
6	1	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
7	1	None	Medium	Unknown	4x6	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
8	1	None	Medium	Unknown	5x5	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
9	1	None	Medium	Unknown	5x5	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
10	1	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
11	1	None	Medium	Unknown	3x3	Adjacent to fence. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
12	1	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
13	1	Low	Medium	2-4	5x10	Anomaly comprised of multiple small GPR reflections and EM anomalies indicating possible area of scattered debris.
14	1	None	Low	Unknown	5x30	Possible Utility
15	1	Low	Medium	1-4	7x30	Anomaly comprised of multiple small GPR reflections and EM anomalies indicating possible area of scattered debris.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
16	1	None	Medium	Unknown	5x3	Sharp increase and decrease in EM response, indicating small, near surface targets. Based on low to medium levels of response, is expected that this is an area of minor, near surface metallic debris.
17	1	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
18	1	None	Low	Unknown	5x5	Based on low to medium levels of response, it is expected that this is an area of minor, near surface metallic debris.
19	1	None	Medium	Unknown	5x5	Based on low to medium levels of response, it is expected that this is an area of minor, near surface metallic debris.
20	1	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
21	1	None	Medium	Unknown	7x10	Larger EM anomaly seen on two parallel transect lines. May be comprised of 2 individual anomalies.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
22	1	None	Low	Unknown	3x3	Small EM-61 anomaly evident on two EM transect lines. Anomaly may be associated with leach pool LPH-C. May be an area of minor, near surface metallic debris or associated with former LPH-C.
23	1	None	Medium	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
24	1	Low	Medium	1-2	20x40	Anomaly comprised of multiple small GPR reflections and EM anomalies indicating possible area of scattered debris.
25	1	Low	Medium	1-3	7x10	Anomaly comprised of multiple small GPR reflections and EM anomalies indicating possible area of scattered debris.
26	3	None	Medium	Unknown	10x10	Larger EM anomaly seen on three parallel transect lines.
27	3	None	Low	Unknown	5x7	Minor area of debris
28	3	None	Medium	Unknown	7x7	Corresponds to former drywell DRY-E. Evident on 3 EM transect lines.
29	3	None	Medium	Unknown	40x40	Large EM anomaly comprised of multiple smaller EM anomalies. May be an area of scattered metallic debris or former foundation.

Table 1 – Summary of Geophysical Survey Results

Anomaly ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
30	3	None	Medium	Unknown	5x5	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
31	3	None	Low	Unknown	5X5	Probably associate with nearby reinforced concrete pad.
32	3	None	Low	Unknown	3x5	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
33	3	None	Medium	Unknown	5x8	Probably associate with nearby reinforced concrete curb.
34	3	None	Low	Unknown	3x3	Small EM-61 anomaly with rapid increase and decrease of the EM response. Only evident on one EM transect line. Suspected to be an area of minor, near surface metallic debris.
35	3	Minor	Medium	1-3	3x3	Anomaly is located within a larger, rectangular EM-61 anomaly, which may be associated with a former building foundation.
36	3	None	Medium	Unknown	5x20	Along Cantiague Rock Road. Anomaly may be associated with Utility.

Table 1 – Summary of Geophysical Survey Results

Target ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
DRYH-A	1, 2	Did Not Survey	Could not survey due to reinforced concrete	Unknown		The reported location of former drain DRYH-A was within the northeast portion of Building 140. Was not surveyed because of limited depth of penetration of GPR signal on the interior of the buildings.
DRY-B	1, 2	None	High	Unknown		EM-61 Anomaly is associated with existing catch basin. It is possible that DRY-B is the existing catch basin.
DRYH-C	3, 4	High	Interference from metal fence	2-4	2x2	A GPR was identified 5 ft to the northeast of the reported location of former drywell DRYH-C. The location of this anomaly is shown as GPR Anomaly D on Figure 4.
DRY-D	3, 4	None	High	Unknown		EM-61 Anomaly is associated with existing catch basin. It is possible that DRY-D is the existing catch basin.
DRY-E	3, 4	None	Medium	Unknown	7x7	A circular EM-61 anomaly was identified at the reported location of former drywell DRY-E. The location of this anomaly is shown on Figure 3 as EM-61 Anomalies 28.
LPH-A	1, 2	None	Interference from existing reinforced concrete pad	Unknown		Limited depth of penetration of GPR signal due to existing reinforced concrete pad.

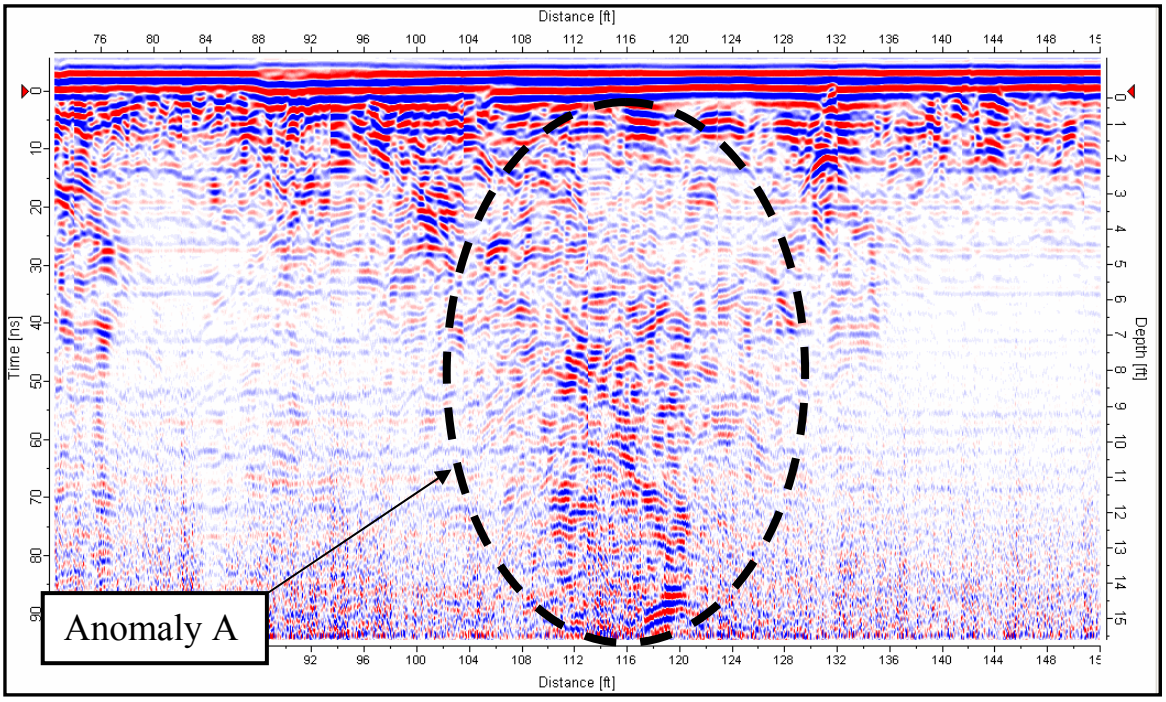

Table 1 – Summary of Geophysical Survey Results

Target ID	Figure Number	GPR Response	EM-61 Response	Estimated Depth (feet)	Estimated Size of Anomaly Area (feet)	Comments
LPH-B	1, 2	Low	Medium	Unknown		Two geophysical anomalies were identified near the reported location of former leach pool LPH-B. The locations of these two anomalies correspond to Anomalies 1 and 2.
LPH-C	1, 2	Medium	None	Unknown		Reported location corresponds to Anomaly 22. Evident on 2 EM-61 transect lines.
DRH-A	1, 2	High	Not Surveyed	2-4	3x3	The reported location of former drain DRH-A was within the central portion of Building 140. One GPR anomaly was located in the vicinity of the reported drain. The GPR data was of poor quality due to the reinforced concrete floor. The location of the GPR anomaly is shown on Figure 2 as GPR Anomaly G.
DRH-B	1, 2	None	Could not survey due to reinforced concrete	Unknown		Reported to be located on interior of Building 100. Limited depth of penetration of GPR signal due to reinforced concrete.

APPENDIX 2
DESCRIPTION OF GEOPHYSICAL METHODS, SURVEY METHODOLOGIES AND LIMITATIONS

A2.1 On Site Measurements

The measurements that were collected and used to create the site map were made using a fiberglass measuring tape. The degree of accuracy of such an approach is typically +/-5% for lengths and +/-2.5 degrees for angles.

A2.2 Time Domain Electromagnetics

The TDEM (EM-61) method evaluates the magnitude of an induced (secondary) electromagnetic (EM) field caused by a primary EM field after that primary field is suddenly shut off.

During a TDEM (EM-61) sounding, an electrical current is caused to flow in a horizontal transmitter coil located near the ground. The current is maintained until a static magnetic field is established. The current in that coil is then rapidly terminated. This produces a strong electromotive force that induces eddy (secondary) currents in the ground. The eddy currents are caused by the presence of subsurface conductors. With increasing time, the strength of the eddy currents diminishes. The eddy currents, when they are still present induce a voltage in the receiver coil that is proportional to eddy current strength. The eddy current strength also depends on the amount of metal in the subsurface. The more metal present, the longer the eddy currents persist. Field measurement consists of reading the output voltage from the receiver coil registered at a particular time after field shut-off. If no metal is present near the coil, then there are no eddy currents at a late time and the reading is near zero. If metal is present near the coil, then the eddy currents persist for a longer time, and the reading is some positive number. By sensing only the response from the buried metal, the method is capable of detecting targets in highly conductive environments. For TDEM surveys the Geonics Ltd. Model EM-61 metal detection (EM-61) system is used. The EM-61 instrument response is recorded on field-portable computerized data logger (Polycorder Digital Data Recorder) for subsequent data processing and contouring.

The EM-61 survey is performed along predetermined transect lines. The transect lines are typically uni-directional and oriented parallel to the long axis of the site. The spacing between transects ranges from 2 to 5 ft, depending upon the desired size of the target to be identified. Approach is typically +/-5% for both lengths and angles in degrees.

A2.3 Ground Penetrating Radar

Ground Penetrating Radar (GPR) consists of a set of integrated electronic components that transmits high frequency (200 to 1500 megahertz [MHz]) electromagnetic waves into the ground and records the energy reflected back to the ground surface. The GPR system consists of an antenna, which serves as both a transmitter and receiver, and a profiling recorder that both processes the incoming signal and provides a graphic display of the data. The GPR data can be reviewed as both printed hard copy output or recorded on the profiling recorder's hard drive for later review. GeoView uses a Mala GPR system.

A GPR survey provides a graphic cross-sectional view of subsurface conditions. This cross-sectional view is created from the reflections of repetitive short-duration electromagnetic (EM) waves that are generated as the antenna is pulled across the ground surface. The reflections occur at the subsurface contacts between materials with differing electrical properties. The electrical property contrast that causes the reflections is the dielectric permittivity that is directly related to conductivity of a material. The GPR method is commonly used to identify such targets as underground utilities, underground storage tanks or drums, buried debris, voids, rebar or geological features.

The greater the electrical contrast between the surrounding materials (earth or concrete) and target of interest, the greater the amplitude of the reflected return signal. Unless the buried object is metal, only part of the signal energy will be reflected back to the antenna with the remaining portion of the signal continuing to propagate downward to be reflected by deeper features. If there is little or no electrical contrast between the target interest and surrounding earth materials it will be very difficult if not impossible to identify the object using GPR.

A GPR survey is conducted along survey lines (transects) which are measured paths along which the GPR antenna is moved. Electronic marks are placed in the data by the operator at designated points along the GPR transects. These marks allow for a correlation between the GPR data and the position of the GPR antenna on the ground.

For buried debris surveys, the GPR survey is conducted along a set of perpendicularly orientated transects. The survey is conducted in two directions. This is because the most definitive GPR signal response indicating the presence of a buried object is obtained when the GPR antenna is passed perpendicular to the long axis of the buried object.

Depth estimates to the top of the debris is determined by dividing the time of travel of the GPR signal from the land surface to the top of the GPR signal

reflection associated with the debris by the velocity of the GPR signal. The velocity of the GPR signal is usually obtained from published tables of the GPR signal traveling through unsaturated soils (4 to 6 nano-seconds per foot two-way travel time). The accuracy of GPR-derived depths typically ranges from 20 to 40 percent of the total depth.

The analysis and collection of GPR data is both a technical and interpretative skill. The technical aspects of the work are learned from both training and experience. Interpretative skills for debris studies are developed by having the opportunity to compare GPR data collected in numerous settings to the results from confirmatory studies performed at the same locations.

The ability of GPR to collect interpretable information at a project site is limited by the attenuation (absorption) of the GPR signal within subsurface soil materials. Once the GPR signal has been attenuated at a particular depth, information regarding deeper features will not be obtained. GeoView can make no warranties or representations of geological conditions that may be present beyond the depth of investigation or resolving capability of the GPR equipment or in areas that were not accessible to the geophysical investigation.

GeoView can make no warranties or representations of the conditions that may be present beyond the depth of investigation or resolving capability of the TDEM or GPR equipment or in areas that were not accessible to the geophysical investigation.

Radiation Surveys Inside Building 70

This page intentionally left blank.

Sylvania Corning FUSRAP Site – Phase I RI

Radiation Surveys Inside Building 70

This technical memorandum addresses the results of the radiation surveys performed inside Building 70.

1.0 SURVEY METHODOLOGY

1.1 Overview

Radiation surveys inside Building 70 were performed September 11 through 15, 2006. Surveys included verification measurements at locations with elevated radiation levels identified during a radiological characterization survey performed in 2003 and as new surveys in the rear warehouse (not previously surveyed) and within building drains and other floor penetrations in Building 70.

All surveys were performed in accordance with safety procedures as outlined in the September 2006 *Site Safety and Health Plan – Remedial Investigation Phase I for the Sylvania Corning FUSRAP Site*. Surveys included surface scans and static measurements for alpha, beta, and gamma radiation at specific locations and direct gamma measurements within accessible drains. Radiation dose rates were also measured throughout the building.

1.2 Equipment

Equipment used to perform radiological surveys included the following:

- Ludlum Model- 2360 portable ratemeter/scaler with Ludlum Model 43-93 alpha/beta scintillation detector
- Ludlum Model 14C portable ratemeter with Ludlum Model 44-9 geiger-mueller (GM) detector.
- Bicron MicroRem dose ratemeter.
- Ludlum Model 2221 ratemeter/scaler with a Model 44-10-5, 2-inch by 2-inch sodium iodide (NaI) scintillation detector.

1.3 Quality Control Measures

Quality control (QC) measurements for field instrumentation included initial response to a radioactive source and daily operability checks. All instruments were calibrated within the last twelve months by the instrument vendor, a certified calibration laboratory, using sources traceable to the National Institute of Standards and Technology (NIST). Calibration certificates for each instrument are provided in Attachment 1. Prior to commencing any surveys, ten initial readings were collected on each detector using technicium-99 (^{99}Tc), thorium-230 (^{230}Th), and cesium-137 (^{137}Cs) sources to establish control charts for each unit to determine daily

operability. The bases for the daily operability of these instruments are ± 20% of the average for the initial ten measurements for the 44-9 and 44-10-5 probes and ±3-sigma of the average for the initial ten measurements for the 43-93. These data are included in Attachment 1.

All field instruments satisfactorily passed the daily QC checks, with one exception. During post-job review of the instrument QC data, it was observed that the Ludlum 2360/43-93 combination was found to be outside of ±3-sigma on 9/14/06. The field technician inadvertently applied a 'qualitative' ±20% criterion to the daily QC data for this instrument, which showed a passing result. However, when applying the more stringent ±2 and ±3 sigma criteria used for quantitative field instruments, the daily alpha source check failed. If the technician had known that the count failed, the count would have been repeated in accordance with CABRERA procedures. Further inspection of the data by the CABRERA project Health Physicist shows that this particular count was 13 counts per minute (cpm) above the +3-sigma control line, corresponding to a 3.2 sigma result. Since this value does not appear to represent a severe instrument deficiency or malfunction, it was determined that the survey data performed on 9/14/06 does not need to be disqualified.

1.4 Acceptable Levels of Surface Contamination

Table 1 provides acceptable surface contamination limits for various radionuclides as applied to surface contamination measurements. The most conservative values (transuranics) were used because the predominant radiological contaminants of potential concern are thorium and uranium. The alpha removable contamination limit is 20 disintegrations per minute per 100 square centimeters (dpm/100cm^2), while the maximum and average contamination limit is 300 and 100 dpm/100cm^2, respectively. The beta-gamma removable contamination limit is 1,000 dpm/100cm^2.

It should be noted that surveys of the drains within Building 70 were not compared with the surface contamination levels in Table 1. Since the drain surveys were performed for gamma radiation, technicians were advised to be cognizant of readings that exceeded twice the observed background levels in unaffected areas within Building 70.

Table 1: Acceptable Levels of Surface Contamination

Radionuclide[a]	Acceptable Surface Contamination Levels (DPM/100 cm^2)		
	Removable[b, e]	Average[b, c]	Maximum[b, d]
Transuranics, ^{226}Ra, ^{227}Ra, ^{230}Th, ^{228}Th, ^{231}Pa, ^{221}Ac, ^{125}I, ^{129}I	20	100	300
Th-Natural, ^{232}Th, ^{90}Sr, ^{223}Ra, ^{224}Ra, ^{232}U, ^{126}I, ^{131}I, ^{133}I	200	1,000	3,000
U-Natural, ^{235}U, ^{238}U, and associated decay products	1,000 α	5,000 α	15,000 α
Beta-Gamma emitters (radionuclides with decay modes other than alpha emission or spontaneous fission) except ^{90}Sr and others noted above.	1,000 β γ	5,000 β γ	15,000 β γ

Taken from Table 6-4 of USACE Radiation Protection Manual EM-385-1-80.

a Where surface contamination by both alpha- and beta-gamma emitting nuclides exists, the limits established for alpha- and beta-gamma emitting nuclides should apply independently.
b As used in this table, dpm (disintegrations per minute) means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.
c Measurements of average contaminant should not be averaged over more than 1 square meter. For objects of less surface area, the average should be derived for each object.
d The maximum contamination level applies to an area not more than 100 cm^2.
e The amount of removable radioactive material per 100 cm^2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency. When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionately and the entire surface should be wiped.

2.0 RESULTS

The results of all contamination surveys are provided in Attachment 2. All surveys were labeled using the same grid system for Building 70 developed and used during the previous scoping efforts in 2003. For reference, a map of the scoping survey results performed in 2003 is provided as Figure 1. The grids are referenced by the building support beams located throughout all of the survey areas, e.g., F6, E9, etc. Multiple points within a given grid node are sequentially numbered.

Results of the verification measurements are summarized on Figure 2. The locations of all of the previously identified surface contamination areas were reconfirmed with either the alpha/beta scintillation detector or the gamma scintillation detector. Only beta and gamma radiation were measured, which confirmed the original survey findings that the contamination is contained underneath surface coatings or within the expansion joints of the concrete floors. At the F3

location, although readings were elevated, the spot identified originally is believed to be underneath a new divider wall installed since the original survey.

The results of the drain and penetration gamma surveys are illustrated in Attachment 2, Figure 3. All measurements were consistent with ambient background levels. The walkover gamma radiation survey around the perimeter of the eastern warehouse and over the footprint of the former recharge basin yielded background radiation levels. All radiation dose rates, measured at a height of approximately 1 meter above the ground, were at background levels.

Walkover Gamma Radiation Survey for Exterior Areas of Building 70

This page intentionally left blank.

Sylvania Corning FUSRAP Site – Phase I RI

Walkover Gamma Radiation Survey

Building 70 Exterior Areas

This technical memorandum addresses the results of the Building 70 exterior walkover gamma radiation survey.

1.0 WALKOVER GAMMA RADIATION SURVEY

The Building 70 walkover gamma radiation survey (walkover survey) was performed to assess the potential for elevated radiological contaminants of potential concern for the Sylvania Corning FUSRAP Site, specifically isotopes of thorium and uranium. The survey was performed over 100% of reasonably accessible areas surrounding Building 70. A total of 6771 square meters (or 1.67 acres) were surveyed. Approximately 70% of the total area had an asphalt surface, while the remainder was grass. Several small concrete areas were also surveyed, but the overall area was very small.

1.1 Equipment

The walkover survey was performed using a Ludlum Model 2221 ratemeter connected to a 3-inch by 3-inch sodium iodide (NaI) gamma scintillation detector. NaI detectors are well suited for exterior surveys of uranium and thorium isotopes.

The ratemeter/detector combination was connected to a Trimble Pro XRS global positioning system (GPS) receiver and configured such that correlated gamma count rate and geospatial location were recorded once every second during the survey. The GPS was operated such that positional accuracy to 1 meter was maintained throughout the survey. The minimum detectable concentration (MDC) capabilities of the system are outlined in Attachment 1.

1.2 Quality Control Measures

Quality control (QC) measurements for field instrumentation included initial response to a radioactive source and daily operability checks. All instruments were calibrated within the last twelve months by the instrument vendor, a certified calibration laboratory, using sources traceable to the National Institute of Standards and Technology (NIST). Calibration certificates for each instrument are provided in Attachment 2. Prior to commencing the walkover survey, ten initial readings were collected on each detector using a cesium-137 (^{137}Cs) source to establish a control chart for each unit to determine daily operability. The basis for daily operability for instruments of this type is ± 20% of the average for the initial ten measurements. These data are included in Attachment 2.

The GPS system was configured using the North American Datum 1983 (NAD83), State Plane coordinate system for New York Long Island (3104) in units of meters. Operability of the GPS was determined by the available satellite coverage and associated position dilution of precision (PDOP) reported by the GPS handset. If the PDOP was observed to rise above 6, the surveyor immediately paused and waited for the PDOP to improve. PDOP increases are a direct result of line-of-sight interference between the GPS satellites and the receiver.

1.3 Survey Methodology

The walkover survey was performed in accordance with the CABRERA project procedure provided in Attachment 1. The ratemeter, detector, and GPS were all mounted on a converted walk behind a 'baby-jogger' platform. The GPS receiver was placed inside the seat of the baby jogger with the antenna protruding vertically directly over the detector. This method served to improve the quality of the walkover survey data by eliminating variations in detector height and position and reducing operator errors due to fatigue. The walkover survey was performed by walking straight parallel paths over the designated areas. Survey passes were approximately 1 meter apart (the distance between the rear wheels). The operator used orange traffic cones or other markers to help maintain consistent path spacing between passes. While walking the survey paths, the surveyors visually observed the GPS signal reception status. In the event of GPS signal loss, the surveyors paused until signal was regained.

Data from the ratemeter/scaler was automatically logged into the GPS until the desired survey area was completed.

1.4 Data Processing

All field GWS data was forward to the CABRERA project Health Physicist for review and evaluation. The data compiled during the Building 70 GWS was verified to be complete and usable without qualification. The reviewed survey data was then imported into a geographic information system (GIS) software program for post-processing and imaging. Post-processing of the data included calculation of descriptive statistics including mean, standard deviation, and z-scores. A z-score is the difference of the count rate in counts per minute (cpm) from each acquisition and the mean of the count population divided by the standard deviation of the population, as shown in Equation 1 below.

$$Z = \frac{(L_{cr}) - (M_{ds})}{(STDEV)} \qquad \text{(Eq 1)}$$

where: Z = Z-score

L_{cr} = Count rate, in gross cpm, of local acquisition

M_{ds} = Mean of the data set, in gross cpm

STDEV= Standard deviation of the dataset

Imaging of the prepared data displayed spatial coordinates (plotted on the X and Y axes) and Z-scores of the gamma readings (plotted on the Z axis). The software generated a spatially

interpolated contour map depicting calculated Z-scores of the composite dataset. Locations with Z-scores greater than 3 were investigated as candidates for additional sampling and characterization activities.

2.0 RESULTS

During the course of the walkover survey, a total of 28,003 data points were collected from three ratemeter detector combinations. Meter SN 176952 collected 15,317 data points, having an average of 14,753 cpm, a standard deviation of 2,598 cpm, and a maximum of 35,196 cpm. Meter SN 1183465 collected 3,860 data points, having an average of 16,040 cpm, a standard deviation of 1,561 cpm, and a maximum of 21,351 cpm. Detector SN 132861 collected 8,825 data points, having an average of 16,483 cpm, a standard deviation of 2,341 cpm, and a maximum of 29,259 cpm. The overall average was found to be 15,346 cpm with a standard deviation of 2,531 cpm. Z-scores of the complete dataset ranged from -2.46 to 6.39.

The graphical representation of the dataset is shown on the Z-score contour plot in Attachment 3. A majority of the area surrounding Building 70 was found to be below one z-score, suggesting that there is little variability in the radiological constituents over the survey area.

Four general areas were found to have Z-scores greater than 3, shown as orange on the contour plot. These areas are summarized in Table 1.

Table 1. Summary of Walkover Survey Area with Z-Score > 3

Location	Description
1	Grass area to the northwest of Building 70 near gate to Cantiague Rock Road
2	Northwest corner of parking lot near north entrance door
3	Grass area between west boundary of Building 70 and Cantiague Rock Road
4	Small grass area at the southwestern property boundary

None of the above areas are believed to be real sources of residual contamination from former Sylvania operations. The following points support this conclusion:

- The elevated Z-scores shown for Areas 2 and 3 are most likely being biased by contributions from the brick facing used on the outside of Building 70 and, possibly, the concrete walkway. The NaI detectors used to perform the walkover survey were not shielded or collimated to eliminate contributions from sources beyond what is found directly below the detector face. Biases of this type are relatively easy to characterize and eliminate once they are understood and accounted for. Follow-up surveys in Areas 2 and 3 with shielded NaI detectors could be performed during Phase II of the RI, with

results compared with the unshielded detector. Several soil samples are already planned for these areas as part of the Building 70 characterization.

- The Z-score plot shows gross gamma count rates for multiple surfaces (asphalt, concrete, and grass). Each of these surfaces has a representative natural background range associated with it. Combining multiple areas into a single dataset can sometimes draw attention to one of these areas as a potential residual contamination area. Areas 1 and 4 are both grassy areas within a larger asphalt data set having lower average count rates. The grassy areas had count rates only 5,000 cpm above the larger data set. If the walkover survey is performed in the future, reference area surveys will be performed on similar surfaces to obtain gamma signatures for each type of surface.

This page intentionally left blank.

Gamma Walkover Surveys

Purpose

The purpose of the GWS is to identify areas of elevated radioactivity. Surficial scans, where possible, are particularly effective at identifying spatial trends in surficial contamination and potential $DCGL_{emc}$ concerns. These types of surveys have been used with considerable success at other USACE FUSRAP sites with similar radiological contaminants of concern.

Equipment

Equipment required for performing the GWS survey includes the following:

- Trimble Pathfinder Pro - XRS (or equivalent)
- 2x2 or 3x3 NaI detector and associated rate-meter/scaler, equipped with RS-232 or USB download port;
- Hardware: IBM-compatible Pentium (minimum) personal computer, color printer, large capacity data storage device (e.g., CD-ROM), large format plotter, (note that some hardware may not be site-based).
- Software: Trimble Pathfinder Office, GIS software (ArcGIS or equivalent) with coordinate geometry capability.

Methods

The survey will be performed following MARSSIM protocol by walking straight parallel lines over an area while moving the detector in a serpentine motion, 0.05 to 0.10 m (2 to 4 in) above the ground surface. Survey passes will be approximately one meter apart. Data from the ratemeter/scaler will be automatically logged into the GPS unit once per second. After completion of the survey, the raw data will be downloaded from the GPS and sent to a data processing specialist for export into a geospatial software program. After completion of data processing, an electronic file with the contoured results of the survey will be returned to the FSM for evaluation.

The GWS data will then be forwarded to the CABRERA Technical Lead for evaluation after field data processing. Gamma walkover survey data will be delivered to E&E and USACE in graphical format (maps of count rate contours by easting and northing in US State Plane feet, New York Long Island, NAD83). This evaluation will determine if any GWS anomalies exist that warrant further investigation by collecting biased surface soil samples for laboratory radioanalysis. Anomalies identified will be reported to the CABRERA PM, or designee, for evaluation and concurrence. Anomaly locations will be forwarded to the field team, and will be physically marked for follow-up.

Before a detection system is utilized for surveys, it is necessary to perform an *a priori* calculation of the Scan Minimum Detectable Concentration (Scan MDC) for the system. The nominal Scan MDC for a Ludlum Model 44-20 3x3 NaI detector for U-238 has been calculated to be approximately 4 pCi/g.

This page intentionally left blank.

Estimation of Scan Minimum Detectable Concentrations (MDCs) for Gamma Walkover Surveys at the Sylvania-Corning FUSRAP Site

This page intentionally left blank.

1. Introduction

A MARSSIM based scoping survey plan was implemented by Cabrera Services, Inc. (CABRERA), under contract to Ecology & Environment (E&E) for properties in Hicksville, NY to determine whether they have been affected by the former operations conducted by Sylvania-Corning. The purpose of this document is to estimate gamma walkover scan sensitivities for the Radionuclides of Concern (ROCs), particularly Natural Uranium with Short-Lived Progeny and Uranium-235 (U-235). The specific objective is to estimate the scan sensitivity of a gamma walkover survey performed using a 3-in by 3-in sodium iodide (NaI) scintillation detector to measure ROCs at the Site. The method is first demonstrates for Cesium-137 (Cs-137), as this is the nuclide to which the NaI detectors are calibrated.

2. Estimation of Minimum Detectable Concentrations (MDC)

This document utilizes the methodology and approach documented in MARSSIM (Section 6.7.2.2, Table 6.7) for a 2-in x 2-in NaI scintillation detector. MARSSIM calculations for the 2-in x 2-in detectors are based on NRC NUREG-1507, *Minimum Detectable Concentrations with Typical Radiation Survey Instruments for Various Contaminants and Field Conditions* (NRC 1997). MARSSIM Table 6.7 does not provide scan MDCs for 3-in x 3-in NaI detectors; thus scan MDCs are derived using MARSSIM/NUREG-1507 methods. Factors included in this analysis are the surveyor scan efficiency, index of sensitivity, the natural background of the surveyed area, scan rate, detector to source geometry, areal extent of the potential hot spot(s), and energy and yield of gamma emissions.

The computer code Microshield was used to model the presence of a normalized 1 pCi/g of Cs-137, total uranium and short-lived progeny, and U-235 in soil with the assumption that the activity was uniformly distributed to a depth of 15 cm and spread over a disk shaped area with a diameter of 56 cm. This is consistent with the NUREG-1507 methodology and provides for a count rate to exposure ration (CPM/μR/hr) to be calculated. As the Site consists of paved areas, the model includes attenuation and energy loss through asphalt. Activity concentrations must be entered into Microshield in units of $\mu Ci/cm^3$ with consideration to the density of soil at 1.6 g/cm^3. Therefore, activity concentrations for Cs-137, total uranium with short-lived progeny, and U-235 were entered into Microshield as 1.6E-6 $\mu Ci/cm^3$ with decay times sufficient to allow in-growth of progeny activities.

$$1\ pCi/g \times 1E\text{-}6\ \mu Ci/pCi \times 1.6\ g/cm^3 = 1.6E\text{-}6\ \mu Ci/cm^3$$

The Microshield exposure rate output is included as an attachment to this Appendix.

Two scenarios were considered for estimating the uranium scan MDC. Fully enriched uranium metal (i.e. 100% U-235) and natural uranium ore with short-lived progeny. When uranium is extracted from ore, it disrupts the equilibrium between the parent and

daughter nuclides. Because some of the daughter radionuclides in both the U-235 and U-238 decay chains have large half-lives (~10^4 yr), it takes several years for the equilibrium to be reestablished. For the case where equilibrium with short lived progeny, U-235 was assumed to be in equilibrium with only Th-231, and U-238 was assumed to be in equilibrium with Th-234, and Pa-234/234m. U-234, U-235, and U-238 are assumed to exist at natural activity fractions (i.e. 0.489, 0.022, and 0.489, respectively). Therefore, isotopic uranium activity concentrations of 7.83E-7 μCi/cm^3, 3.47E-8 μCi/cm^3, and 7.83E-7 μCi/cm^3, respectively, to represent 1 pCi/g of total uranium.

For the fully enriched case, U-235 was used at a concentration of 1.6E-6 μCi/cm^3 to represent a total activity of 1 pCi/g.

A set of tables are attached, based upon the NUREG-1507 methodology as applied toward a 3-in x 3-in NaI scintillation detector. Additional details and discussion describing the NUREG analysis methodology are described in that publication.

2.1. Fluence Rate to Exposure Rate (FRER)

The fluence rate to exposure rate (FRER) may be approximated by:

$$FRER \approx \frac{1\mu R/hr}{(E_\gamma)(\mu_{en}/\rho)_{air}}$$

Where:

E_γ	=	energy of the gamma photon of concern, keV
(μ_{en}/ρ)	=	the mass energy absorption coefficient for air, cm^2/g

This can be represented in tabular form, as in Table 1.

2.2. Probability of Interaction (P) Through Detector End for a Given Energy

The probability, P, of a gamma ray interaction in the NaI scintillation crystal entering through the end of the crystal is given by:

$$\Pr obability(P) = 1 - e^{-(\mu/\rho)_{NaI}(X)(\rho_{NaI})}$$

Where:

$(\mu/\rho)_{NaI}$	=	the mass attenuation coefficient for NaI
X	=	the thickness through the end of the 3-in x 3-in NaI crystal, 7.62 cm
(ρ_{NaI})	=	the density of the NaI crystal, 3.67 g/cm^3

This can be represented in tabular form, as in Table 2.

2.3. Relative Detector Response (RDR)

The Relative Detector Response (RDR) as a function of energy is determined by multiplying the relative fluence rate to exposure rate (FRER) by the probability (P) of an interaction and is given by:

$$RDR = (FRER)(P)$$

This can be represented in tabular form, as in Table 3.

2.4. Determination of CPM per μR/hr as a Function of Energy

The equivalent FRER, P, and finally RDR may be calculated for the NaI scintillation detector at the Cesium-137 (Cs-137) energy of 662 keV. Manufacturers of this equipment typically provide an instrument response in terms of CPM and μR/hr at the Cs-137 energy. This point allows one to determine the CPM per μR/hr and ultimately activity concentration and minimum detection sensitivity level in terms of pCi/g for a specific instrument.

Based on a manufacturer's 3-in x 3-in NaI response specification (Ludlum 44-20) of 2,700 CPM/μR/hr, and using the same methodology as shown in the tables above, the FRER, P, and RDR are calculated. The mass energy absorption coefficient for air and the mass attenuation coefficient for NaI are interpolated from tables in the Radiological Health Handbook, Revised Edition January 1970, pages 139, and 140.

FRER	$Energy_{\gamma}$, keV	$(\mu_{en}/\rho)_{air}$, cm^2/g
0.0514	662	0.0294

$(\mu_{en}/\rho)_{NaI}$, cm^2/g
0.0780

P
0.89

And Cs-137 RDR (662 keV) = 0.0456

The detector response (CPM) to another energy is based upon the ratio of the RDR at a specific energy to the known CS-137 energy RDR:

$$CPM/\mu R/hr, E_i = \frac{(CPM/\mu R/hr_{Cs-137})(RDR_{E_i})}{(RDR_{Cs-137})}$$

This can be represented in tabular form, as in Table 4.

2.5. Minimum Detectable Count Rate

The minimum detectable count rate (MDCR) is calculated using the NUREG-1507 methodology where:

The average number of background counts in a one second interval, b_i = CPM/60

And for the Ludlum generic count rate to exposure rate ratio value of 2,700 CPMμR/hr and 10μR/hr measured background gives:

$$B_i = (10\mu R/hr)(2{,}700\ CPM/\mu R/hr)/(60) = 450\ counts$$

The background exposure rate of 10 μR/hr is used as a conservative estimate for the property. Background exposure rates vary but are typically less than 10 μR/hr.

The MDCR is therefore calculated as:

$$MDCR = (d')(b_i)^{0.5}(60sec/1min)$$

Where d' is from Table 6.1 of NUREG-1507 and represents the rate of detections at 95% and a false positive rate of 60%, and b_i is the background counts, giving:

$$MDCR = (1.38)(450)^{0.5}(60) = 1{,}756\ CPM$$

The MDCR for the surveyor is given as:

$$MDCR_{surveyor} = MDCR / (P)^{0.5}$$

Where P is the surveyor efficiency equal to 0.5 to 0.75 as given by NUREG-1507. 0.5 was chosen as a conservative estimate and

$$MDCR_{surveyor} = 1{,}756 / (0.5)^{0.5} = 2{,}483\ CPM$$

The count rate to exposure ratio for each of the Uranium with short-lived progeny and the U-235 gamma emissions and their contributions to the total exposure rate may be computed using the output of the Microshield runs and the count rate to exposure rate ratios from Table 4.

2.6. Estimate of Cs-137 Scan MDC

The Microshield runs are summarized in Table 5 for Cs-137. The minimum detectable exposure rate from Cs-137 is obtained from the $MDCR_{surveyor}$ divided by the Table 5 weighted count rate to exposure rate value of 3,003 CPM/μR/hr for a 1 pCi/g normalized concentration.

2,483 CPM / 3,003 CPM /μR/hr = 0.83 μR/hr

The scan MDC is then equal to the ratio of the Minimum Detectable Exposure Rate in the field to the exposure rate determined for the normalized 1 pCi/g concentration of Cs-137.

$$ScanMDC = \frac{(Normalized_Cs_{conc})(ExposureRate_{surveyor})}{(ExposureRate_{normalized_Cs_conc})}$$

Scan MDC = (1 pCi/g)(0.83 μR/hr)/(0.131 μR/hr) = **6.34 pCi/g**

2.7. Estimate of Uranium with Short-lived Progeny Scan MDC

The Microshield runs are summarized in Table 6 for uranium with short-lived progeny. The minimum detectable exposure rate from uranium with short-lived progeny is obtained from the $MDCR_{surveyor}$ divided by the Table 6 weighted count rate to exposure rate value of 2,533 CPM/μR/hr for a 1 pCi/g normalized concentration.

2,483 CPM / 2,533 CPM /μR/hr = 0.98 μR/hr

The scan MDC is then equal to the ratio of the Minimum Detectable Exposure Rate in the field to the exposure rate determined for the normalized 1 pCi/g concentration for uranium and short-lived progeny.

$$ScanMDC = \frac{(Normalized_U_{conc})(ExposureRate_{surveyor})}{(ExposureRate_{normalized_U_conc})}$$

Scan MDC = (1 pCi/g)(0.98 μR/hr)/(0.238 μR/hr) = **4.12 pCi/g**

2.8. Estimate of U-235 Scan MDC

The Microshield runs are summarized in Table 7 for uranium with short-lived progeny. The minimum detectable exposure rate from U-235 is obtained from the $MDCR_{surveyor}$ divided by the Table 7 weighted count rate to exposure rate value of 11,950 CPM/μR/hr for a 1 pCi/g normalized concentration.

2,483 CPM / 11,950 CPM /μR/hr = 0.208 μR/hr

The scan MDC is then equal to the ratio of the Minimum Detectable Exposure Rate in the field to the exposure rate determined for the normalized 1 pCi/g concentration for U-235.

$$ScanMDC = \frac{(Normalized_U_{conc})(ExposureRate_{surveyor})}{(ExposureRate_{normalized_U_conc})}$$

Scan MDC = (1 pCi/g)(0.208 μR/hr)/(0.0224 μR/hr) = **9.28 pCi/g**

3. Summary

Using the NUREG-1507 methodology, the calculated scan MDCs for the 3-in x 3-in NaI scintillation detector employed for this radiological survey are as follows:

Radionuclide	Scan MDC (pCi/g)
Cs-137	6.34
Uranium with Short-lived Progeny	4.12
U-235	9.28

Sylvania Corning FUSRAP Site – Phase I RI

Radiation Contamination Surveys

All Site Areas

This technical memorandum addresses the results of the radiation-contamination surveys performed during installation and retrieval of passive soil gas probes around the exterior of Buildings 70, 100, and 140, and active soil gas probes inside Building 70 at the Sylvania Corning FUSRAP site.

1.0 SURVEY METHODOLOGY

1.1 Overview

Radiation contamination surveys were performed September 11 through 15, 2006 and on September 25 and 26, 2006. Contamination surveys were performed on equipment and personnel to assess the potential for elevated radiological contaminants of potential concern, specifically, isotopes of thorium and uranium, during intrusive sampling activities. Surveys for fixed and removable contamination were performed during installation and retrieval of active and passive soil gas probes and during collection of samples at the Building 70 transformer area.

All surveys were performed in accordance with safety procedures as outlined in the September 2006 *Site Safety and Health Plan – Remedial Investigation Phase I for the Sylvania Corning FUSRAP Site*. Surveys included surface scans and static measurements for alpha and beta radiation, wipes for removable alpha and beta contamination, and collection of representative background measurements for all surveyed surfaces.

1.2 Equipment

Equipment used to perform contamination surveys included the following:

- Ludlum Model- 2360 and 2224-1 portable ratemeter/scaler with Ludlum Model 43-93 alpha/beta scintillation detectors.
- Ludlum Model 14C portable ratemeter with Ludlum Model 44-9 geiger-mueller (GM) detector.

\

1.3 Quality Control Measures

Quality control (QC) measurements for field instrumentation included initial response to a radioactive source and daily operability checks. All instruments were calibrated within the last twelve months by the instrument vendor, a certified calibration laboratory, using sources traceable to the National Institute of Standards and Technology (NIST). Calibration certificates for each instrument are provided in Attachment 1. Prior to commencing any surveys, ten initial readings were collected on each detector using technicium-99 (^{99}Tc) and thorium-230 (^{230}Th) sources to establish a control chart for each unit to determine daily operability. The bases for the daily operability of these instruments are ± 20% of the average for the initial ten measurements for the 44-9 probe and ±3-sigma of the average for the initial ten measurements for the 43-93. These data are included in Attachment 1.

All field instruments satisfactorily passed the daily QC checks, with one exception. During post-job review of the instrument QC data, it was observed that the Ludlum 2360/43-93 combination was found to be outside of ±3-sigma on 9/14/06. The field technician inadvertently applied a 'qualitative' ±20% criterion to the daily QC data for this instrument, which showed a passing result. However, when applying the more stringent ±2 and ±3 sigma criteria used for quantitative field instruments, the daily alpha source check failed. If the technician had known that the count failed, the count would have been repeated in accordance with CABRERA procedures. Further inspection of the data by the CABRERA project Health Physicist shows that this particular count was 13 counts per minute (cpm) above the +3-sigma control line, corresponding to a 3.2 sigma result. Since this value does not appear to represent a severe instrument deficiency or malfunction, it was determined that the survey data performed on 9/14/06 does not need to be disqualified.

1.4 Acceptable Levels of Surface Contamination

Table 1 provides acceptable surface contamination limits for various radionuclides as applied to surface contamination measurements. The most conservative values (transuranics) were used because the predominant radiological contaminants of potential concern are thorium and uranium. The alpha removable contamination limit is 20 disintegrations per minute per 100 square centimeters (dpm/100cm^2), while the maximum and average contamination limit is 300 and 100 dpm/100cm^2, respectively. The beta-gamma removable contamination limit is 1,000 dpm/100cm^2.

.

\

Table 1: Acceptable Levels of Surface Contamination

Radionuclide[a]	Acceptable Surface Contamination Levels (DPM/100 cm^2)		
	Removable[b, e]	Average[b, c]	Maximum[b, d]
Transuranics, ^{226}Ra, ^{227}Ra, ^{230}Th, ^{228}Th, ^{231}Pa, ^{221}Ac, ^{125}I, ^{129}I	20	100	300
Th-Natural, ^{232}Th, ^{90}Sr, ^{223}Ra, ^{224}Ra, ^{232}U, ^{126}I, ^{131}I, ^{133}I	200	1,000	3,000
U-Natural, ^{235}U, ^{238}U, and associated decay products	1,000 α	5,000 α	15,000 α
Beta-Gamma emitters (radionuclides with decay modes other than alpha emission or spontaneous fission) except ^{90}Sr and others noted above.	1,000 β γ	5,000 β γ	15,000 β γ

[a] Where surface contamination by both alpha- and beta-gamma emitting nuclides exists, the limits established for alpha- and beta-gamma emitting nuclides should apply independently.
[b] As used in this table, dpm (disintegrations per minute) means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.
[c] Measurements of average contaminant should not be averaged over more than 1 square meter. For objects of less surface area, the average should be derived for each object.
[d] The maximum contamination level applies to an area not more than 100 cm^2.
[e] The amount of removable radioactive material per 100 cm^2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency. When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionately and the entire surface should be wiped.

2.0 RESULTS

The results of all contamination surveys are provided in Attachment 2. Individual data worksheets are provided for background measurements collected at the site, Building 70 soil gas support surveys, and exterior soil gas support surveys. A summary map of the Building 70 interior surveys is also provided.

Calculation of disintegrations per minute per 100 square centimeters (dpm/100cm^2) integrated a 300-cm survey area because all removable contamination surveys utilized large area, i.e., masselin, wipes instead of smaller, folder-type smears. Masselin surveys are advantageous for surveys of this kind because much larger areas can be surveyed for removable contamination, which increases the probability of detection.

The only data flags that occurred during the surveys were results of the alpha scans on wipes of the boring equipment at exterior soil gas locations 45 (84.1 dpm/100cm^2) and 81 (56

\

dpm/100cm^2). However, it is unlikely that these events are true positives for removable alpha contamination, based on the supporting evidence. First, the flagged values are near or below the calculated alpha minimum detectable concentrations (MDC) for the model 43-93 detector. The lowest MDC achievable for the 43-93 is 27 dpm/100cm^2, given zero counts per minute background (see Attachment 1). MDC levels between 27 and 102 dpm/100cm^2 were calculated for the range of alpha background levels measured during the morning QC activities. Furthermore, both of these locations were shallow soil borings (6 inches) west and south of Building 70 and the beta results at these locations were both at background. It is more likely that the elevated alpha counts at these locations were due to natural background fluctuations.

COMMENTS:

Alpha Sens.:120mv
Beta Sens.:3.5mv
Beta Window:30mv
H.V. set with detector disconnected.
Firmware;390096
instrument calibrated with 5' cable.
EFF. for: Th230=22%, Tc99=21%, Ni63=0.13%, Sr90Y90=36%
4 pi efficiencies (refer to plateau sheet for details).
Overload set to simulate light leak.

Gamma Calibration: GM detectors positioned perpendicular to source except for M 44-9 in which the front of probe faces source.

1.0 INTRODUCTION

The Sylvania Corning site (hereafter referred to as the 'Site') occupies 10.5 acres divided into three contiguous properties located at 70, 100, and 140 Cantiague Rock Road, in the westernmost portion of Hicksville, Long Island, approximately 30 miles east of lower Manhattan. Industrial and commercial properties adjoin the Site to the north (the Nassau County Department of Public Works), to the south (General Instruments' inactive waste disposal site, currently unoccupied), to the west by Cantiague Rock Road, and to the east by the golf driving range of Cantiague Park.

The Site was added to the Formerly Used Sites Remedial Action Program (FUSRAP) in 2006 to evaluate radioactive contamination resulting from former operations conducted under contract to the federal government. The US Army Corps of Engineers (USACE), Kansas City District has responsibility for the FUSRAP investigation of the Site. Ecology and Environment, Inc. (E & E) has been contracted by USACE to conduct a remedial investigation of uranium and thorium contamination at the Site.

This page intentionally left blank.

2.0 SCOPE OF WORK

Cabrera Services, Inc. (CABRERA) has been contracted by E & E to perform Health Physics (HP) support services for the second phase of the FUSRAP remedial investigation at the Site. These services included the performance of soil core scanning surveys, Downhole Gamma Logging (DGL) surveys, and providing radiological support for the following activities:

- Leach pool/drain/drywell investigations;
- Collection of confirmatory borings in remediation cells;
- Collection of borings in data gap areas of the Building 70 property;
- Collection of borings in the area between Building 100 and Building 140;
- Concrete coring investigations in Building 70;
- Test pit excavations to investigate geophysical anomalies at the Site.

The results of these activities were used to assist sample location efforts in the field, ensure worker health and safety, and to provide radiological data for the draft RI report.

This page intentionally left blank.

3.0 SURVEY METHODOLOGY

To accomplish the scope of work, CABRERA provided two teams of two personnel each. The first team consisted of Albert Craig and Kevin Andrews (Site Safety & Health Officer). The second team was comprised of Derrick Albert and Gordon Tannahill (Field Site Manager and Site Radiation Safety Officer). All work was performed in accordance with *Final Remedial Investigation Work Plan (Phase I & Phase II) for the Sylvania Corning FUSRAP Site, 2007* (WP) and CABRERA procedures.

3.1 Soil Core Scanning Surveys

Soil sample cores were scanned for ambient gross gamma radiation using a lead shielded Ludlum Model 44-10 sodium-iodide (NaI) probe connected to a Ludlum Model 2221 ratemeter/scaler. Soil cores were placed in a counting jig and scanned at a rate of one to two inches per second. Scanning results were recorded on data sheets in increments of one foot at the location of highest activity in that increment. Local background measurements were collected for the 44-10 detector within the jig at each borehole.

3.2 Downhole Gamma Logging

Sample boreholes were surveyed for gross gamma radiation using a Bicron Model G1 1x1 NaI probe connected to a Ludlum Model 2221 ratemeter/scaler. Once the target depth was reached by the drilling contractor, each sample borehole was sleeved with 1.5-in outside diameter (OD) poly-vinyl chloride (PVC) pipe. The pipe was used to maintain the integrity (i.e., prevent collapse) of the borehole once the sample barrel and drilling rods were removed from the hole. One-minute integrated measurements were collected in one foot increments within the borehole, relative to the bottom, and recorded on a data sheet. An integrated one minute reference measurement was performed at the surface of each borehole. All gamma logging surveys were performed in accordance with CABRERA procedures.

3.3 Radiological Support

3.3.1 Routine Radiological Monitoring

Radiological controls were maintained and contamination monitoring was performed by team members during all sampling and subsurface activities. Radiological controls included posting and implementation of exclusion zones (EZ) surrounding work areas, treating all equipment in work areas as if contaminated, and performing release surveys on all equipment and personnel exiting from an EZ. Contamination monitoring was performed throughout work activities to identify potential contamination as soon as possible. Routine contamination monitoring results were compared to the acceptable levels of surface contamination (See Section 3.4). All contamination monitoring was performed in accordance with CABRERA procedures and the approved WP (E & E, 2007).

Routine monitoring included the following:

- Ambient Gamma Monitoring (Ludlum Model 19 exposure rate meter)
- Masselin Cloth (Ludlum Model 2221 ratemeter/scaler with 43-93 α/β probe)

- Surface scans (Ludlum Model 12C with 44-9 β/γ probe and Ludlum Model 2221 with 43-93 probe)
- Frisking of Personnel and Equipment (Ludlum Model 12C with 44-9 β/γ probe and Ludlum Model 2221 with 43-93 α/β probe)
- Swipe Samples (Ludlum Model 2929)

In addition to routine contamination monitoring, surveys for free release of materials and equipment were performed for equipment leaving the site. Free release survey results were compared to the acceptable levels of surface contamination (See Section 3.4). All free release surveys were performed in accordance with CABRERA procedures and the WP (E & E, 2007).

3.3.2 Monitoring During Test Pitting

Exclusion zones were set up around the test pit work areas and pre-excavation surveys were performed with Ludlum Model 2221 ratemeter/scalers with 44-10 NaI probes and Ludlum Model 19 detectors. Plastic sheeting was laid over the asphalt so that the spoils could be surveyed. Soil was scanned using a Ludlum Model 44-10 probe and Ludlum Model 19 in the bucket before being placed on the spoils pile. Once a uniform depth of soil had been removed from the test pit, the spoils from that depth were spread out on the plastic, visually examined, and scanned again using a 44-10 probe and Model 19. Routine contamination monitoring was performed throughout the excavation process.

3.3.3 Building 70 Concrete Core Removal

The Phase I investigation identified seven floor locations in Building 70 with elevated surface activity. Cores from these seven locations were collected as part of the Phase II investigation. Cores were bored through the concrete to the soil below the slab. If an expansion joint was present at the location, the core was drilled such that the expansion joint ran the diameter of the bit.

Prior to drilling, sample locations were posted as EZ and sectioned off with yellow and magenta rope. Personnel inside the restricted area donned tyvek suits, rubber booties, and gloves for contamination control purposes. Four inch diameter concrete cores were drilled and removed under continuous HP coverage. Water use during boring operations was required for cooling and dust suppression, but was kept to a minimum. All water used during coring activities was collected via absorbent pads. Absorber pads, PPE, and materials used in restricted areas were collected and packaged as rad waste. Cores were placed in plastic bags during storage.

3.4 Acceptable Levels of Surface Contamination

Table 1 provides acceptable surface contamination limits for various radionuclides as applied to surface contamination measurements. The most conservative values (transuranics) were used since the predominant radionuclides of potential concern are thorium and uranium. The alpha removable contamination limit is 20 disintegrations per minute per 100 square centimeters (dpm/100cm^2), while the maximum and average contamination limit is 300 and 100 dpm/100cm^2, respectively. The beta-gamma removable contamination limit is 1000 dpm/100cm^2.

TABLE 1: ACCEPTABLE LEVELS OF SURFACE CONTAMINATION

Radionuclide[a]	Acceptable Surface Contamination Levels (DPM/100 cm^2)		
	Removable[b, e]	Average[b, c]	Maximum[b, d]
Transuranics, ^{226}Ra, ^{227}Ra, ^{230}Th, ^{228}Th, ^{231}Pa, ^{221}Ac, ^{125}I, ^{129}I,	20	100	300
Th-Natural, ^{232}Th, ^{90}Sr, ^{223}Ra, ^{224}Ra, ^{232}U, ^{126}I, ^{131}I, ^{133}I	200	1,000	3,000
U-Natural, ^{235}U, ^{238}U, and associated decay products	1,000 α	5,000 α	15,000 α
Beta-Gamma emitters (radionuclides with decay modes other than alpha emission or spontaneous fission) except ^{90}Sr and others noted above.	1,000 β γ	5,000 β γ	15,000 β γ

Taken from Table 6-4 of USACE Radiation Protection Manual EM-385-1-80.

a Where surface contamination by both alpha- and beta-gamma emitting nuclides exists, the limits established for alpha- and beta-gamma emitting nuclides should apply independently.

b As used in this table, dpm (disintegrations per minute) means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.

c Measurements of average contaminant should not be averaged over more than 1 square meter. For objects of less surface area, the average should be derived for each object.

d The maximum contamination level applies to an area not more than 100 cm^2.

e The amount of removable radioactive material per 100 cm^2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency. When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionately and the entire surface should be wiped.

This page intentionally left blank.

4.0 RESULTS

4.1 Soil Core Scanning Surveys

Sample core scan results were used to aid in the selection of biased samples. Each sample core was scanned and the area of highest activity was marked on the core and recorded on the data sheet. A total of 180 core scan surveys were performed at the Site. Core scan results ranged from a minimum of 1,100 cpm to a maximum of 9,000 cpm on the shielded 44-10 NaI detector. The median range for individual boreholes was 300 cpm. Four boreholes (i.e., F6-01, 100-11, 140-06, and SU-08-06) had core scan results with a range of 1,000 cpm or greater.

A summary of soil core scan results by borehole is presented in Attachment 1. Electronic copies of all Soil Core Scanning Survey data sheets are located on the attached Data compact disk (CD).

4.2 Downhole Gamma Logging Surveys

A total of 163 DGL surveys were performed at the Site. DGL results ranged from a minimum of 623 cpm to a maximum of 29,106 cpm. The median range of the DGL results within the boreholes was 1,895 cpm. A summary of DGL results by borehole is presented in Attachment 1. Electronic copies of all DGL data sheets are located in Attachment 2 on the attached Data CD.

4.3 Radiological Support

4.3.1 Contamination Monitoring

All sampling and subsurface activities were monitored for the presence of elevated radiological activity. Results of routine contamination monitoring were recorded in site log books. All of the routine removable contamination monitoring results were below the applicable limits in Table 1. Electronic copies of the site logbooks with routine contamination monitoring results are located in Attachment 2 on the attached Data CD. All routine contamination monitoring was performed in accordance with CABRERA procedures and the WP (E & E, 2007).

In addition to the sampling support activities, all equipment leaving the site was surveyed for free release. Equipment that was surveyed for free release included drilling rigs, backhoes, and all associated support equipment. Survey results for all release surveys were below the applicable removable release criteria in Table 1. Electronic copies of all radiological release surveys are located in Attachment 2 on the attached Data CD.

4.3.2 Test Pits

A total of ten test pits were excavated at the site. Soil scanning results ranged from 1,300 cpm to 6,500 cpm with a shielded Ludlum 44-10 NaI probe. Table 2 summarizes the survey results for each test pit. Five of the test pits (EM-3, EM-5, EM-15-1B, EM-29A, and GPR-F) identified elevated levels of radioactivity. Descriptions of the findings within each of these pits are provided in the following paragraphs. An electronic copy of the radiological survey forms of the test pits is located in Attachment 2 on the attached Data CD.

In Test Pit EM-3, approximately 20 linear feet of 3-in diameter pipe with internal contamination was identified at a depth of approximately 3’ 3-ft below ground surface (bgs). Exposure rate

measurements of the pipe were up to 20 μR/hr on contact and 5 μR/hr at one meter from the pipe with an ambient background of 5 μR/hr. The highest scan result from the end of a section of pipe was 3,000 β/γ cpm with a Ludlum Model 44-9 with an instrument background of 40 β/γ cpm. The exposure rate on a soil sampled pulled from the interior of the pipe was 35 μR/hr on contact. The lengths of pipe were bagged on both ends and placed inside a double bagged drum. The exposure rate on the drum was 10 μR/hr on contact and 5 μR/hr at one meter. Swipe measurements collected from the interior of the pipes and the work area were below the applicable limits in Table 1, indicating that the contamination is fixed.

In Test Pit EM-5, a four foot section of 3-in diameter pipe with internal contamination was identified at a depth of approximately 2 ft bgs. Exposure rate measurements of the pipe were background on contact. The highest scan result from the end of the pipe was 4,000 β/γ cpm with a Ludlum Model 44-9, relative to a local background count rate of 40 β/γ cpm. The exposure rate on a soil sampled pulled from the interior of the pipe was 35 μR/hr on contact. The pipe was double bagged and fitted into a drum to be disposed of as radioactive waste. Masselin results collected from the interior of the pipes and the work area were below the applicable limits in Table 1.

Test Pit EM-15-1B had elevated soil at a depth of 1-ft to 3-ft bgs. The elevated material was found to present in between two asphalt layers. Mixed in the soil was greenish salt like material that appeared to be the source of the elevated readings. Small amount (i.e., 0.5 grams) of the salt was collected and had a direct beta/gamma reading of 800 β/γ cpm with a Ludlum 44-9. On the face of the trench wall, the exposure rate was up to 70 μR/hr on contact and 5 μR/hr at one meter from the face of the trench. The elevated soil that was excavated from between the asphalt layers was loaded into three drums and labeled as radioactive waste. Each drum had an exposure rate of 10 μR/hr on contact and 5 μR/hr at one meter. Masselin results collected from the work area were all below the applicable limits in Table 1.

In Test Pit EM-29A, a small (e.g., 5-30 gallon) drum carcass or container was found at a depth of approximately 3-ft bgs. The remains of the crushed and rusted container was in two pieces with one piece measuring approximately 2-ft by 2-ft and the other piece being 1.5-ft by 1-ft. A survey of the drum identified elevated alpha and beta/gamma activity in the seams and folds of the carcass. The drum read 15 μR/hr on contact and 5 μR/hr at one meter. A static count of the drum bung with a Ludlum 43-93 was approximately 60 α dpm/100cm^2 and 17,450 β/γ dpm/100cm^2. Masselin results of the drum and general area were below the applicable limits in Table 1. The drum carcass appeared to have lead shielding associated with it. The carcass and surrounding soil were double bagged and placed in a separate drum for storage as suspect radioactive waste.

In Test Pit GPR-F, soil scanning identified a hardened "nugget" with elevated activity at a depth of approximately 3-ft bgs. The shielded Ludlum 44-10 reading on contact with the nugget was 60,000 γ cpm. The nugget was 70 μR/hr on contact and 5 μR/hr at one meter. The nugget had static alpha/beta count rates of 42 dpm/100cm^2 and 350 dpm/100cm^2 with the Ludlum 43-93, respectively and 80,000 β/γ dpm/100cm^2 with the Ludlum 44-9. The nugget and immediate soil were double bagged and placed in a drum as radioactive waste along with the with the drum carcass from EM-29A.

TABLE 2: TEST PIT SURVEY RESULTS

Date	Location ID	Total Depth (ft)	Minimum 44-10 Result (cpm)	Maximum 44-10 Result (cpm)	Maximum Exposure Rate (µR/hr)
6/14/07	EM-2	4	1,600	3,000	6
6/14/07	EM-3	7	1,900	3,000	6
6/14/07	EM-5	4	1,800	2,400	6
6/13/07	EM-15-1A	3	1,600	3,000	10
6/13/07	EM-15-1B	7	1,000	6,500	70
6/12/07	EM-21	7	1,200	1,800	5
6/11/07	EM-26	4	1,800	2,600	6
6/11/07	EM-29A	7	2,100	6,500	15
6/11/07	EM-29B	4	2,000	2,400	5
6/12/07	GPR-F	4	1,800	2,500	70

4.3.3 Building 70 Concrete Core Removal

Initial surveys were performed at locations G4-01, F3-01, F6-01, F6-02, D9-01, A3-01 and D8-02. Elevated activity was confirmed on surface areas and in the expansion joints of the concrete slabs. Ambient exposure rates at sample locations ranged from 5 to 50 µR/hr on contact. Static measurements of surface activity ranged up to 127 α dpm/100cm^2 and 235,860 β/γ dpm/100cm^2 with the Ludlum Model 43-93. No removable activity above the applicable limits in Table 1 was identified at these sample locations.

At location D9-01, elevated activity was identified in the top 3-in of the expansion joint. The highest reading on the core was 1,500 cpm β/γ with the Ludlum Model 44-9 and a surface exposure rate of 5 µR/hr. Elevated activity was present in the expansion joint on both sides of the hole after the core was removed. At the bottom of the hole, a 1-min integrated result with the shielded Ludlum 44-10 was 14,000 cpm. No removable activity above the applicable limits in Table 1 was found after sampling was completed.

At boring location A6-01, elevated activity was identified the throughout the expansion joint (i.e., 4-in). Elevated activity was also identified on the soil below the slab. The core sample had a surface count rate of 35,000 β/γ cpm with the Ludlum Model 44-9 and an exposure rate of 20 µR/hr on contact. Soil at the bottom of the hole appeared elevated with a shielded Ludlum 44-10 result of 20,000 γ cpm in contact with the soil. Given these levels, the Geoprobe unit was brought in to collect subsurface soil samples at this location. Soil core screening identified elevated activity in the first 2 to 3 ft of soil with results of up to 9,000 cpm on the shielded 44-10. The Geoprobe hit refusal at approximately 7-ft bgs. Soil core screening results returned to background levels (~2,100 cpm) between 4-ft and 7-ft bgs.

For boreholes A3-01, D8-02, F6-02, A3-01, and G4-01, core readings ranged from 100 to 35,000 cpm β/γ with a Ludlum Model 44-9. Instrument readings at the bottom of the boreholes ranged from 2,730 cpm to 4,746 γ cpm with the shielded Ludlum 44-10.

5.0 QUALITY CONTROL

5.1 Quality Control Measures

Quality control (QC) measurements for field instrumentation included initial response to a radioactive source and daily operability checks. All instruments were calibrated within the last twelve months by the instrument vendor, a certified calibration laboratory, sources traceable to the National Institute of Standards and Technology (NIST). Calibration certificates for each instrument are provided on the attached Data CD.

Prior to commencing any surveys, ten (10) initial readings were collected on each detector using Technicium-99 (^{99}Tc) and Thorium-230 (^{230}Th) sources to establish a control chart for each unit to determine daily operability. The bases for the daily operability of these instruments are ± 20% of the average for the initial ten measurements for the Ludlum Model 44-9 probe, Ludlum Model 44-10 probe, Bicron G1 probe, and Ludlum Model 19 detector and ±3-sigma of the average for the initial ten measurements for the Ludlum Model 43-93 probe and Ludlum 2929 detector. These data are included in Attachment 2. All field instruments satisfactorily passed the daily QC checks.

TECHNICAL MEMORANDUM

Results of Phase IIB Radiological Surveys and Support
Sylvania Corning FUSRAP Site
Hicksville, New York

Prepared for:

Ecology and Environment, Inc.
368 Pleasant View Drive
Lancaster, NY 14086

Prepared by:

CABRERA SERVICES
RADIOLOGICAL · ENVIRONMENTAL · REMEDIATION

103 East Mount Royal Ave, Suite 2B
Baltimore, MD 21202

February 2008

This page intentionally left blank.

1.0 INTRODUCTION

The Sylvania Corning site (hereafter referred to as the 'Site') occupies 10.5 acres divided into three contiguous properties located at 70, 100, and 140 Cantiague Rock Road, in the westernmost portion of Hicksville, Long Island, approximately 30 miles east of lower Manhattan. Industrial and commercial properties adjoin the Site to the north (the Nassau County Department of Public Works), to the south (General Instruments' inactive waste disposal site, currently unoccupied), to the west by Cantiague Rock Road, and to the east by the golf driving range of Cantiague Park.

The Site was added to the Formerly Used Sites Remedial Action Program (FUSRAP) in 2006 to evaluate radioactive contamination resulting from former operations conducted under contract to the federal government. The US Army Corps of Engineers (USACE), Kansas City District has responsibility for the FUSRAP investigation of the Site. Ecology and Environment, Inc. (E & E) has been contracted by USACE to conduct a remedial investigation of uranium and thorium contamination at the Site.

This page intentionally left blank.

2.0 SCOPE OF WORK

Cabrera Services, Inc. (CABRERA) was contracted by E & E to perform health physics (HP) support services for Phase IIB of the FUSRAP remedial investigation at the Site. These services included the performance of soil core scanning surveys, down-hole gamma logging (DHG) surveys, and providing radiological support for the following activities:

- Geoprobe drilling using a Geoprobe model 54LT at eight previously probed locations to obtain deeper soil samples (i.e., 16-ft to 24-ft);
- Auger drilling at 13 previously probed Phase IIA locations to obtain deeper soil samples (i.e., 16-ft to 72-ft);
- Auger drilling and combination Geoprobe/auger drilling at 44 new locations (20-ft to 72-ft).
- Test pit excavations at 11 new locations to investigate geophysical anomalies identified during Phase IIA.

CABRERA personnel were on-site to support this scope of work beginning October 15 and continuing through November 21, 2007.

This page intentionally left blank.

3.0 SURVEY METHODOLOGY

CABRERA provided two teams to accomplish the previously defined scope of work. Each team consisted of two personnel; a team leader and a technician. All work was performed in accordance with *Final Remedial Investigation Work Plan (Phase I & Phase II) for the Sylvania Corning FUSRAP Site, 2007* (WP) and applicable CABRERA procedures (incorporated in the E & E work plan).

3.1 Soil Core Scanning Surveys

Sample core scan results were used to aid in the selection of biased samples. Soil sample cores were scanned for gross gamma radiation using a lead shielded Ludlum Model 44-10 2-inch by 2-inch (2x2) sodium-iodide (NaI) probe connected to a Ludlum Model 2221 ratemeter/scaler. Soil cores were placed in a counting jig and scanned at a rate of one to two inches per second. Scanning results were recorded on data sheets in increments of one foot with the highest measured increment noted. Ambient background measurements at each survey area were also recorded for the 44-10 detector to ensure accuracy of the locally recorded data. All soil core scanning surveys were performed in accordance with CABRERA'S soil core scan field procedure.

3.2 Downhole Gamma Logging

Boreholes were surveyed for gross gamma radiation using a Bicron Model G1 1x1 NaI probe connected to a Ludlum Model 2221 ratemeter/scaler. Once the target depth was reached by the drilling contractor, each open borehole was sleeved with 1.5-in outside diameter (OD) poly-vinyl chloride (PVC) pipe. The pipe was used to maintain the integrity of the borehole (i.e., prevent collapse) once the auger or rods were removed. One-minute integrated measurements were collected in one foot increments within the borehole, starting at the bottom, and recorded on a DHG data sheet. All DHG surveys were performed in accordance with CABRERA'S downhole gamma logging field procedure.

3.3 Radiological Monitoring

Radiological controls were maintained and contamination monitoring was performed by team members during all sampling and subsurface activities. All contamination monitoring was performed in accordance with CABRERA procedures and the approved WP (E & E, 2007). Radiological controls included the implementation of exclusion zones surrounding active work areas, treating all equipment in work areas as if contaminated, and performing clearance, i.e.,

free-release, surveys for all equipment and personnel exiting either exclusion zones or the site completely. Radiological monitoring included the following:

- Ambient Gamma Monitoring (Bicron micro-Rem dose rate meter)
- Masselin Cloth (Ludlum Model 2221 ratemeter/scaler with 43-93 alpha-beta scintillation probe)
- Surface scans (Ludlum Model 12C with 44-9 pancake Geiger-Mueller (GM) probe and Ludlum Model 2221 with 43-93 probe)
- Frisking of Personnel and Equipment (Ludlum Model 12C with 44-9 GM probe and Ludlum Model 2221 with 43-93 probe)
- Swipe Samples (Cloth swipes counted on a Ludlum Model 2929 smear counter)

All contamination monitoring results were compared to the acceptable levels of surface contamination provided in Section 3.5.

3.4 Monitoring During Test Pit Excavation

Exclusion zones were set up around the test pits prior to excavation. Pre-excavation surveys of the work areas were performed using an unshielded 44-10 NaI probe, a Ludlum 44-9 GM pancake probe, and Bicron micro-Rem dose rate meter. Plastic sheeting was then laid over an asphalt or gravel area adjacent to the pit location where excavated spoils were to be placed. The plastic sheeting served as an impermeable barrier between the spoils pile and the ground for contamination control purposes. Using the three detectors listed above, excavated soil was scanned in the bucket of the backhoe before being placed on the spoils pile/plastic sheeting. Once a uniform depth of soil had been removed from the test pit, the spoils pile was then spread out to a relatively uniform thickness, visually examined, and scanned again using the suite of detectors.

3.5 Acceptable Levels of Surface Contamination

Table 1 provides acceptable surface contamination limits for various radionuclides as applied to surface contamination measurements. The lowest values (transuranics) in the table were used as a conservative measure despite the fact that the predominant radionuclide of potential concern at this site is uranium. The alpha removable contamination limit used throughout was 20 disintegrations per minute per 100 square centimeters (dpm/100cm^2), while the maximum and average contamination limits are 300 and 100 dpm/100cm^2, respectively. The beta-gamma removable contamination limit is 1000 dpm/100cm^2.

TABLE 1: ACCEPTABLE LEVELS OF SURFACE CONTAMINATION

Radionuclide[a]	Acceptable Surface Contamination Levels (DPM/100 cm^2)		
	Removable[b, e]	Average[b, c]	Maximum[b, d]
Transuranics, ^{226}Ra, ^{227}Ra, ^{230}Th, ^{228}Th, ^{231}Pa, ^{221}Ac, ^{125}I, ^{129}I,	20	100	300
Th-Natural, ^{232}Th, ^{90}Sr, ^{223}Ra, ^{224}Ra, ^{232}U, ^{126}I, ^{131}I, ^{133}I	200	1,000	3,000
U-Natural, ^{235}U, ^{238}U, and associated decay products	1,000 α	5,000 α	15,000 α
Beta-Gamma emitters (radionuclides with decay modes other than alpha emission or spontaneous fission) except ^{90}Sr and others noted above.	1,000 β γ	5,000 β γ	15,000 β γ

Reference: Table 6-4 of USACE Radiation Protection Manual EM-385-1-80.

a Where surface contamination by both alpha- and beta-gamma emitting nuclides exists, the limits established for alpha- and beta-gamma emitting nuclides should apply independently.

b As used in this table, dpm (disintegrations per minute) means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.

c Measurements of average contaminant should not be averaged over more than 1 square meter. For objects of less surface area, the average should be derived for each object.

d The maximum contamination level applies to an area not more than 100 cm^2.

e The amount of removable radioactive material per 100 cm^2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency. When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionately and the entire surface should be wiped.

This page intentionally left blank.

4.0 RESULTS

4.1 Soil Core Scanning Surveys

A total of 66 core scan surveys were performed during the Phase IIB investigation. Core scan results ranged from a minimum of 1,000 cpm to a maximum of 4,350 cpm using a shielded 44-10 NaI detector. The median range of results within a typical borehole was 265 cpm. However, results from Borehole C09-03/D had a range of 2,700 cpm with a maximum value of 4,350 cpm (between 45-ft and 46-ft depth). A visual inspection of this core identified a green salt-like material that appeared to be consistent with contamination found during Phase IIA of the project. The activity of the green salts registered up to 3,000 cpm using a Ludlum 44-9 GM pancake probe. Swipe samples performed on the core sample and the work area did not identify any removable activity in excess of the values listed in Table 1. Spoils from this hole were drummed with labels reading 'pending laboratory analysis,' and stored in the temporary radioactive materials storage area.

A summary of soil core scan results by borehole is presented in Attachment 1. Electronic copies of all completed soil core scanning survey data sheets are included in Attachment 2, a compact disk (CD).

4.2 Downhole Gamma Logging Surveys

A total of 69 DHG surveys were performed during this phase of the project. DHG results ranged from a minimum of 366 cpm to a maximum of 28,391 cpm. The highest DHG result was in borehole C09-03/D at a depth of 47-ft, which corroborated the soil core scanning results from that depth. The median range of results within the boreholes was 1,463 cpm. A summary of DHG results by borehole is presented in Attachment 1. Electronic copies of all DHG data sheets are included on Attachment 2, the electronic Data CD.

4.3 Test Pits

A total of twelve test pits were excavated during Phase IIB. Soil scanning results ranged from a low of 4,300 cpm to a high of 13,700 cpm with an unshielded Ludlum 44-10 NaI probe and from 30 cpm to 1,200 cpm with a Ludlum 44-9 GM pancake probe. Table 2 summarizes the survey results for each test pit. Electronic copies of all test pit survey forms are located on the enclosed data CD. Locations EM-8 and EM-9 were close in proximity and therefore reported on one data sheet (i.e., EM-8/9).

Test Pit EM-28 exhibited the highest activity of all the test pits. EM-28 consisted of a circular concrete dry well that was 7-ft in diameter and 12-ft deep with a concrete bottom. The top of the capped well was detected approximately 3 ft below ground surface. The well was filled to capacity with soil, sand, and building debris. Small particles of elevated activity were identified throughout the well and appeared to be associated with the presence of black soil-like material although not all of the black soil present contained elevated activity. No other features of the elevated activity were visually discernable. No entry or exit pipes or drains were identified within the well.

Scan results on the excavated soils from the well ranged from 30 to 1,200 net cpm on a Ludlum 44-9 GM probe and from 6,000 to 13,700 net cpm with an unshielded Ludlum 44-10. Dose rates on soil ranged from 4 to 8 microRem/hr on contact and at 1-meter, above the spoils. No removable activity in excess of the release criteria was identified in the work area (e.g., backhoe bucket, shovels, sampling equipment, etc.). Soils excavated from the test pit/drywell were returned to the pit with the exception of a volume equivalent to two 55-gallon drums which were segregated and stored in the radioactive materials storage area pending laboratory analysis.

Soil scan results in the remaining test pits ranged from background levels to marginally elevated, as summarized in Table 2.

TABLE 2. TEST PIT SURVEY RESULTS

Location ID	Total Depth (ft)	Ludlum 44-10 Scan Result (cpm)		Ludlum 44-9 Scan Results (cpm)		Dose Rate Range (µrem/hr)
		Min	Max	Min	Max	
EM-35	8	4,500	6,300	30	70	5-7
EM-28	12	6,300	12,000	30	1,200	4-9

EM-13	4	5,800	10,800	40	80	4-8
EM-7	4	4,500	8,130	30	60	3-5
EM-31	5	5,500	6,910	30	80	3-5
EM-8/9	5	4,500	10,500	40	150	3-5
EM-30	4	5,800	7,500	30	60	2-4
EM-34	5	4,500	7,100	40	60	3-4

4.4 Contamination Monitoring

All sampling and subsurface activities were monitored for the presence of elevated radiological activity. Results of routine contamination monitoring were recorded in site log books. All of the routine contamination monitoring results were below the applicable limits listed in Table 1. Electronic copies of the site logbooks with routine contamination monitoring results are included in Attachment 2 on the data CD.

At the request of E & E, two lead-lined drains in Building 70 (DR-BB-1 and DR-BB-2) were surveyed for radiological activity. Both floor drains are approximately 3-inches in diameter and extend approximately 1.5-ft vertically below floor grade, where they connect to a single pipe, extending westward. Elevated activity was identified within both drains. Drain DR-BB-1 measured 600 net cpm using a Ludlum 44-9 GM and had removable activity of 104 alpha and 623 beta dpm/100cm^2 present within the drain. Drain DR-BB-2 measured 400 net cpm using a Ludlum 44-9 and had removable activity of 228 alpha and 802 beta dpm/100cm^2 present within the drain.

A contamination survey (i.e., Radiological Survey #15) was performed in the room containing the drains. This survey confirmed the elevated activity present inside the drains (i.e., survey smears #10 & #11, respectively) but found no removable activity in excess of the values listed in Table 1 in the areas surrounding the drains. Following the survey, yellow and magenta tape was place over the drain covers to indicate the hazard. Electronic copies of Radiological Survey #15 and Cabrera's Smear Counting Worksheet results are presented on the attached Data CD. The data flags present on the Cabrera Smear Counting Worksheet indicate smear results in excess of the values listed in Table 1.

In addition to monitoring sampling and subsurface activities, all equipment leaving the site was surveyed for free release. Equipment that was surveyed for free release included drilling rigs, backhoes, and all associated support equipment. Survey results for all release surveys were below the applicable removable release criteria (i.e., Table 1). Electronic copies of all radiological surveys are located in Attachment 2 on the attached Data CD.

This page intentionally left blank.

5.0 QUALITY CONTROL

5.1 Quality Control Measures

Quality control (QC) measurements for field instrumentation included initial response to a radioactive source and daily operability checks. All instruments were calibrated within the last twelve months by the instrument vendor, a certified calibration laboratory, using sources traceable to the National Institute of Standards and Technology (NIST). Calibration certificates for each instrument are provided in Attachment 2 on the attached Data CD.

Prior to commencing any surveys, ten (10) initial readings were collected on each detector using Technicium-99 (^{99}Tc) and Thorium-230 (^{230}Th) sources to establish a control chart for each unit to determine daily operability. The bases for the daily operability of these instruments were ± 20% of the average for the initial ten measurements for the Ludlum Model 44-9 probe, Ludlum Model 44-10 probe, Bicron G1 probe, and Bicron MicroRem, and ±3-standard deviations from the average for the initial ten measurements for the Ludlum Model 43-93 and Ludlum 2929 detectors.

A review of the alpha/beta counting instrument QC sheets identified instances where instrument response was outside the two sigma value of the initial 10 measurements resulting in a "Question" Flag and one instance on 10/19/08 where the instrument response for detector #196226 exceeded the three sigma value resulting in a "Failure" flag. The QC data was reviewed in the field per Cabrera's *OP-058 Health Physics General Instrument Quality Control Procedure*. The instrument response on 10/19/08 was immediately repeated per procedure and fell within the acceptance criteria. The review of the initial data set on which the control chart was based found the statistical groupings of the initial 10 measurements to be relatively narrow. This narrow grouping resulted in relatively narrow acceptance criteria of two and three sigma. None of the project data was impacted by this occurrence. All quality control data are included electronically on the attached Data CD.

Statement of Certification

MJW Technical Sevices, Inc certifies that the above instrument has been calibrated by standards traceable to the National Institute of Standards and Technology, or to the calibration facilities of other International Standards organization members, or have been derived from accepted values of natural physical constants or have been derived by the ratio type of calibration techniques. The calibration system conforms to the requirements of ANS/NCSL Z540-1-1994 and ANSI N323. The instrument listed above was inspected prior to shipment and it met all the manufacturer's published operating specifications. (MJW technical Services is not responsible for damage incurred during shipment or use of this instrument).

CERTIFICATE OF CALIBRATION

Electroplated Alpha Standard

S.O.# 6481
P.O.# 06-735

Description of Standard:

Model No. DNS-11 Serial No. 2888-01 ✓ Isotope Th-230

Electroplated on polished SS disc, 0.79 mm thick.

Total diameter of 4.77 cm and an active diameter of 4.45 cm.

The radioactive material is permanently fixed to the disc by heat treatment without any covering over the active surface.

Measurement Method:

The 2pi alpha emission rate was measured using an internal gas flow proportional chamber. Absolute counting of alpha particles emitted in the hemisphere above the active surface was verified by counting above, below, and at the operative voltage. The calibration is traceable to NIST by reference to an NIST calibrated alpha source S/N 4001-02.

Measurement Result:

The observed alpha particles emitted from the surface of the disc per minute (cpm) on the calibration date was:

9,720 ± 388

The total disintegration rate (dpm) assuming 1.5% backscatter of alpha particles from the surface of the disc, was:

19,200 ± 766 (0.00863 μCi)

The uncertainty of the measurement is 4 %, which is the sum of random counting error at the 99% confidence level, and the estimated upper limit of systematic error in this measurement.

Electroplated Beta Standard

S.O.# 3759
P.O.# 01-325

Description of Standard:

Model No. DNS-12 Serial No. 2898-01 ✓ Isotope Tc-99

Electroplated on polished SS disc, 0.79 mm thick.

Total diameter of 4.77 cm and an active diameter of 4.45 cm.

The radioactive material is permanently fixed to the disc by heat treatment without any covering over the active surface.

Measurement Method:

The 2pi beta emission rate was measured using an internal gas flow proportional chamber. Absolute counting of beta particles emitted in the hemisphere above the active surface was verified by counting above, below, and at the operative voltage. The calibration is traceable to NIST by reference to an NIST calibrated beta source S/N 2148/90.

Measurement Result:

The observed beta count rate from the surface of the disc per minute (cpm) on the calibration date was:

10,800 ± 432

The total disintegration rate (dpm) assuming 25 % backscatter of beta particles from the surface of the disc, was:

17,300 ± 692 (0.00780 μCi)

The uncertainty of the measurement is 4 %, which is the sum of random counting error at the 99% confidence level, and the estimated upper limit of systematic error in this measurement.

REMEDIAL INVESTIGATION REPORT

APPENDIX C

Photo Logs

Sylvania Corning FUSRAP Site

Hicksville, Nassau County, New York

Prepared for:
UNITED STATES ARMY CORPS OF ENGINEERS
Kansas City District
And
New York District

This page intentionally left blank.

Photograph Description: Typical setup of cart mounted Geoprobe 420M power pack inside Building 70 office space.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 1

Photograph Description: Typical view of truck mounted Geoprobe 66 DT drilling rig inside east warehouse of Building 70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 2

Photograph Description: Typical geoprobe operations on west side of Building 70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 3

Photograph Description: Typical core fixed geometry scanning with 2-inch NaI detector.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 4

Photograph Description: Typical setup of concrete coring machine inside office space in B70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 5

Photograph Description: Radiological scanning of concrete core.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 6

Photograph Description: Typical concrete core section from B70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 7

Photograph Description: View of concrete filled structure (potential sump [SMP-1]) near northwest corner of B70 central warehouse. (SMP-1).

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 8

Photograph Description: Typical view of track mounted Geoprobe 66 DT drilling rig on east side of Building 140.

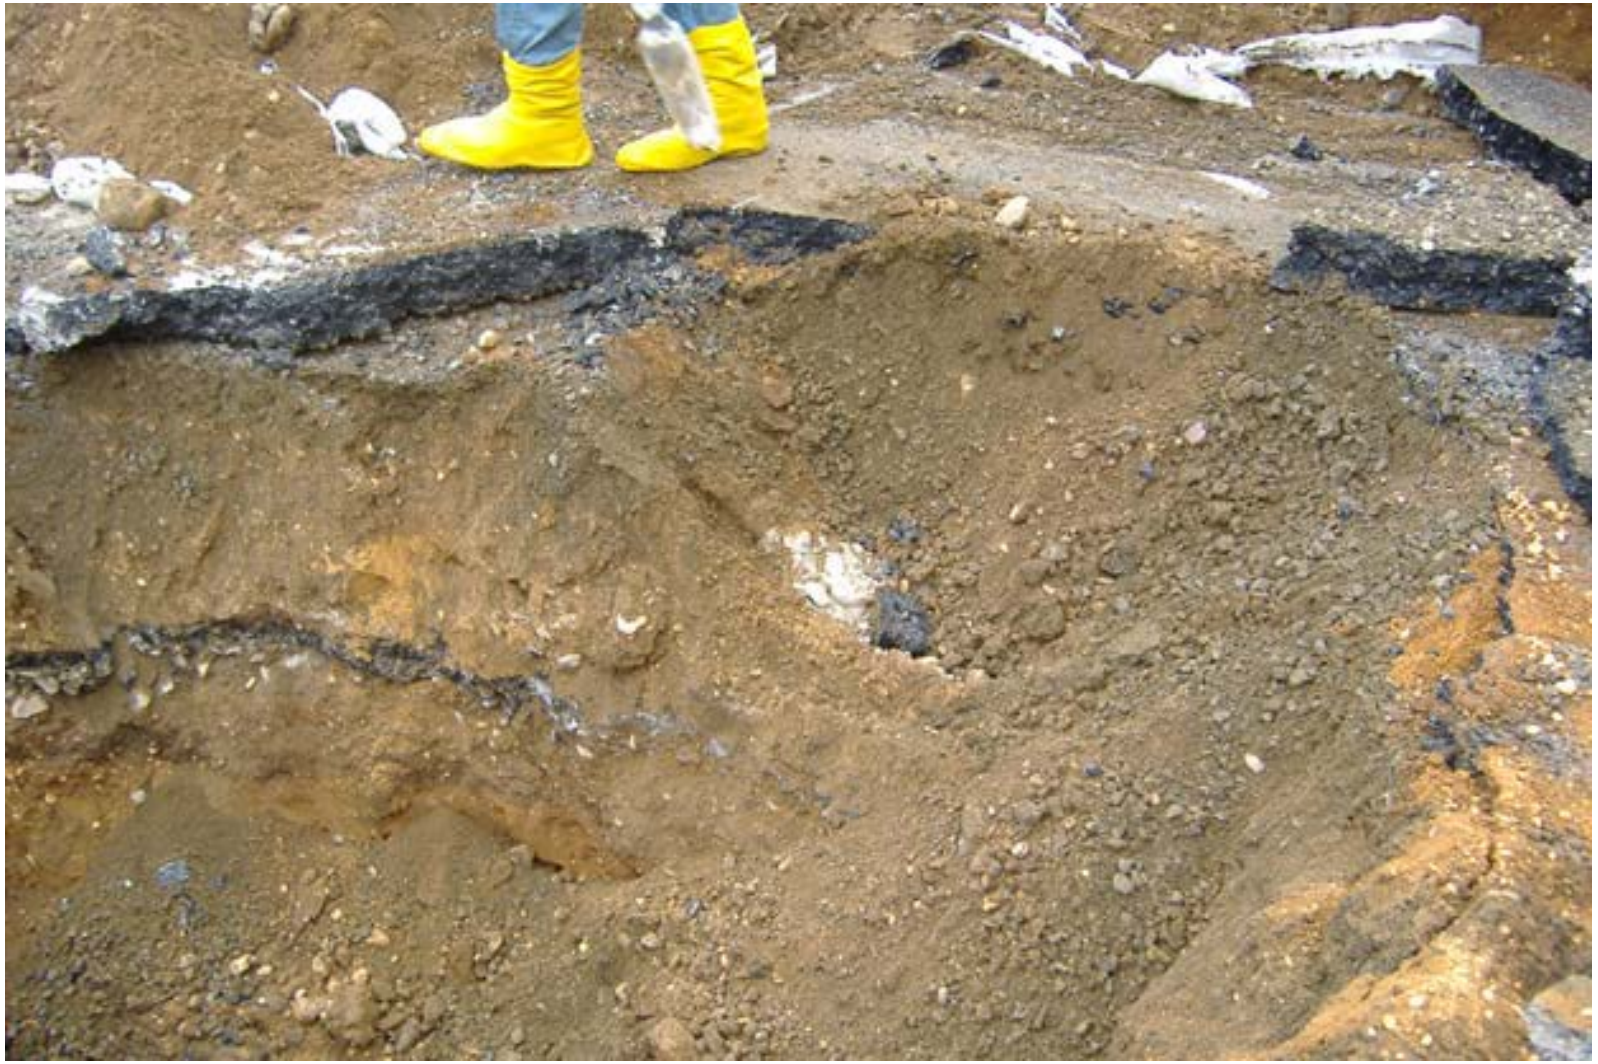
	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 9

Photograph Description: Typical view of test pit scanning with gamma detectors.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 10

Photograph Description: Piping debris from Test Pit EM-2 located between B40 and B100.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 11



Photograph Description: Piping debris in Test Pit EM-3/GPR-A located between B140 and B100.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 12

Photograph Description: Two separate metal pipes located in the shallow subsurface of EM-5. Excavation approximately 2 feet BGS.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 13

Photograph Description: In EM-15b, most elevated radiation levels were shallow (2 feet BGS) above the asphalt layer that may have been a historic parking lot.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 14

Photograph Description: Concrete wall observed in test pit EM-26 located on north side of B70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 15

Photograph Description: Slag “nugget” observed in test pit GPR-F. Note nugget is approximately 3-inches in diameter.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 16

Photograph Description: Excavated to a total depth of 4 feet BGS in GPR-F (both trenches)

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 17

Photograph Description: Drain DR-AA, Note that drain is filled with concrete

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 18

Photograph Description: Drain DR-Z

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 19

Photograph Description: Downhole gamma logging at C12-02

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 20

Photograph Description: Geoprobe at Drain DR-CC

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 21

Photograph Description: Jackhammer driving Macrocore on borehole DR-W

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 22

Photograph Description: Test Pit EM-7

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 23

Photograph Description: Metal pipe removed from Test Pit EM-7 at 1 foot BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 24

Photograph Description: 3 inch diameter metal pipe found at 2 feet BGS in Test Pit EM-7

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 25

Photograph Description: Rebar found in Test Pit EM-8 at approximately 4.5 feet BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 26

Photograph Description: Concrete and metal debris removed from Test Pit EM-8

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 27

Photograph Description: Test Pit EM-9

SYLVANIA CORNING FUSRAP SITE
HICKSVILLE, NASSAU COUNTY, NEW YORK

Photo No.
28

Photograph Description: Concrete debris removed from Test Pit EM-9

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 29

Photograph Description: Test Pit EM-11

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 30

Photograph Description: Test Pit EM-11 excavated to 10 feet BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 31

Photograph Description: Soil excavated from Test Pit EM-11

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 32

Photograph Description: Radiation and PID scan of soil in backhoe from Test Pit EM-13.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 33

Photograph Description: Black staining found at 3 feet BGS in Test Pit EM-13

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 34

Photograph Description: Soil removed from Test Pit EM-13, from approximately 3 feet BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 35

Photograph Description: Metal pipe found in Test Pit EM-13. Pipe runs north-south at approximately 4 feet BGS.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 36

Photograph Description: Black plastic wire conduit found in Test Pit EM-16

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 37

Photograph Description: Test Pit EM-16 showing gray PVC found during excavation

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 38

Photograph Description: Concrete wall found in Test Pit EM-28

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 39

Photograph Description: Soil from Test Pit EM-28 being scanned for radiation

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 40

Photograph Description: Buried drywell found in Test Pit EM-28

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 41

Photograph Description: Crushed lead lined container observed in Test Pit EM-29a on east side of B70

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 42

Photograph Description: Test Pit EM-30

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 43

Photograph Description: Test Pit EM-30

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 44

Photograph Description: 4 inch by 2 foot section of metal pipe found in Test Pit EM-30 at 1 foot BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 45

Photograph Description: 4 inch diameter pipe found at 2 feet BGS in Test Pit EM-31

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 46

Photograph Description: Example of debris found in Test Pit EM-31, at 1 foot BGS

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 47

Photograph Description: Pipe found in Test Pit EM-31

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 48

Photograph Description: Cable found in Test Pit EM-34

SYLVANIA CORNING FUSRAP SITE
HICKSVILLE, NASSAU COUNTY, NEW YORK

Photo No.
49

Photograph Description: Test Pit EM-34 and cable uncovered during excavation

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 50

Photograph Description: View of Test Pit EM-35

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 51

Photograph Description: Pipe found at 1.5 feet BGS in EM-35.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 52

Photograph Description: Vacuum truck removing soil, clearing boring for underground utility lines.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 53

Photograph Description: Video camera survey of DR-E inside B70.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 54

Photograph Description: Soil core from MW-13D (286' to 296').

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 55

Photograph Description: View of setup at offsite well MW-15D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 56

Photograph Description: Soil core from MW-15D. Clay layer from 173’ to 186’.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 57

Photograph Description: Sample filtering for radiation analysis at MW-20D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 58

Photograph Description: Drilling setup at MW-22D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 59

Photograph Description: Drilling setup at MW-22D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 60

Photograph Description: Soil core from MW-31D (277' to 297').

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 61

Photograph Description: E & E personnel collecting groundwater samples from boring 32D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 62

Photograph Description: Setup to begin developing on well MW-26.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 63

Photograph Description: Drilling setup at MW-22I.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 64

Photograph Description: Drilling setup at MW-27D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 65

Photograph Description: Drilling setup at MW-52D on the driving range.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 66

Photograph Description: 24DD

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 67

Photograph Description: Drilling setup on MW-56S on the driving range.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 68

Photograph Description: Well development setup on MW-27I.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 69

Photograph Description: Drilling setup on RI-P-45.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 70

Photograph Description: Drilling setup on 16S.

SYLVANIA CORNING FUSRAP SITE
HICKSVILLE, NASSAU COUNTY, NEW YORK

Photo No.
71

Photograph Description: Installing the designated pump into monitoring well MW-28D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 72

Photograph Description: Groundwater sampling at MW-13D.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 73

Photograph Description: Hand clearing 5 feet before drilling activities commence on a borehole to insure no underground utilities/obstructions are present.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 74

Photograph Description: Drilling setup offsite at MW-213

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 75

Photograph Description: Sonic drilling setup at MW-207. (2012)

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 76

Photograph Description: Sonic drilling setup at MW-217

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 77

Photograph Description: Collection of soil cores into plastic sleeves from a core barrel.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 78

Photograph Description: Typical soil cores seen throughout the project are in plastic sleeves.

	SYLVANIA CORNING FUSRAP SITE HICKSVILLE, NASSAU COUNTY, NEW YORK		Photo No. 79

Photograph Description: Sand transition to clay in a soil core taken at MW-205

Well Development Progress and Deviations Summary

Monitoring Well ID	Date	Minimum Volume (gallons)*	Total Development Water Purged (gallons)	Comments
MW-216-510	10/7/2014	372 (three well volumes; see comments)	115	Well does not produce significant volumes of water and not enough to develop drill water lost during drilling. Presume that drill water lost in area of well placement was into more transmissive areas. Will develop a total of 3 well volumes and stable parameters from the well. 10/16/14 - While 3 well volumes have been removed, turbidity remains elevated (>200 NTUs). 11/10/14 - Sparged well with nitrogen for approximately 4 hours in an attempt to draw fines from sand pack into the well. 11/11/14 - Checked well for sediment buildup (none present), pump well using Monsoon pump. 11/12/14 - No sediments present within the well. Becuase previous attempts have been unsuccessful to increase pumping capacity, no further development is planned.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).

1 well volume (v) = 6.10 gallons. ~~X3 = 18.6~~ 10
4.95 x 3 = 14.85

LOCATION Hicksville, NY — WELL NO. MW201-220

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2 (0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

LOCATION Hicksville, NY WELL NO. MW208-540

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = 94.83 gallons. x 3 = 284.49

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = _____ gallons.

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = 17.135 gallons. x3 = 51.4

LOCATION Wantagh off-ramp / Old Country Rd. WELL NO. MW-220

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).
1 well volume (v) = 76.9 gallons. x3 = 230.76

MEASUREMENT OF WATER LEVEL AND WELL VOLUME

- Prior to sampling, the static water level and total depth of the well will be measured with a calibrated weighted line. Care will be taken to decontaminate equipment between each use to avoid cross contamination of wells.
- The number of linear feet of static water (difference between static water level and total depth of well) will be calculated.
- The static volume will be calculated using the formula:

$$V = Tr^2(0.163)$$

Where:
V = Static volume of well in gallons;
T = Depth of water in the well, measured in feet;
r = Inside radius of well casing in inches;
and 0.163 = A constant conversion factor which compensates for r^2h factor for the conversion of the casing radius from inches to feet, the conversion of cubic feet to gallons, and (pi).

1 well volume (v) = _____ gallons.

Key:
BGS = Below ground surface.
°C = Degrees centigrade.
$CaCO_3$ = Calcium carbonate.
DO = Dissolved oxygen.
mg/L = Milligrams per liter
mV = Millivolts.
NTU = Nephelometric turbidity unit.
ORP = Redox potential.
ppm = Parts per million.
PVC = Polyvinyl chloride.
TOIC = Top of inner (PVC) casing.

250

300 ml/min = purge rate
250 ml/min = sample rate

QA/QC = NA
Dup sample = NA
analysis = U, Th, Ra226/228, TAL Metals, VOCs, Gamma spec, Gross Alpha, Beta
sampler - M. Wroth
1 vol = 39.6 gal
3 vol = 118.9 gal

Groundwater Sample Log

Project: 002260.KZ03.04.07
Site: ~~Former Griffiss Air Force Base~~ Sylvania
Well No.: MW-280
Sample Date: 3-24-07
Sampling Device: ~~QED T1200 bladder pump~~ Geotech Stainless steel pump
Alkalinity (mg/L as $CaCO_3$): NA
Ferrous Iron (mg/L): NA
Initial Water Level (Feet TOIC): 68.63
Final Water Level (feet TOIC):
Casing Type: PVC 2"

Sample ID: MW 280-GW
Sample Time: 1350 (unfiltered + filtered)
Sample Tubing: ~~QED~~ teflon-lined polyethylene
Phenolphthalein Alkalinity (mg/L): NA
Sample Turbidity (NTUs):
Well Depth (feet TOIC): 287
Screen Interval (feet BGS): 277-287
Casing Inner Diameter (inches): 2"
Initial OVA Reading (ppm): 0.0

Time	pH	Temperature (°C)	Conductivity (µs/cm)	Turbidity (NTUs)	DO (mg/L)	ORP (mV)	Water Level (ft TOIC)	Comments (purge vol in liters)

Notes:
[1] VOC - TCL VOCs by method 8260b
[2] Metals - TAL Metals + Hg by methods 6010/6020 and 7470.
[3] Rad+ - Radium 226/228, gamma spectroscopy, gross alpha/beta, isotopic thorium and isotopic uranium

Acronyms:
bgs - below ground surface
DO - Dissolved Oxygen
ID - identification
ft - feet
gpm - gallons per minute
mg/L - milligrams per liter
mV = millivolts
NTU - nephelometric turbidity units
ORP - oxidation-reduction potential
Turb - turbidity
Temp - temperature
ºC - degrees Celcius
µS/cm - microseimens per centimeter. Conductivity corrected to 25 °C.

Time	Purge Volume (L)	pH	Temperature (°C)	Conductivity (µs/cm)	Turbidity (NTUs)	DO (mg/L)	ORP (mV)	Water Level (ft TOIC)	Comments

Key:

BGS = Below ground surface.
°C = Degrees centigrade.
DO = Dissolved oxygen.
mg/L = Milligrams per liter
mV = Millivolts.
NTU = Nephelometric turbidity unit.
ORP = Redox potential.
ppm = Parts per million.
PVC = Polyvinyl chloride.
TOIC = Top of inner (PVC) casing.

Groundwater Sample Log

Site: Sylvania Corning FUSRAP
Well No.: MW-206-470
Sample Date: 6/14/2012
Sampling Device: Bladder Pump
Well Depth (feet TOIC): 470
Screen Interval (feet TOIC):460-470
Initial Water Level (Feet TOIC):61.76
Final Water Level (feet TOIC):61.77
Casing Type: **PVC** Steel (circle one)
Personnel: M. Fronckowiak & T. Dillon

Sample ID: MW-206-470-R1
Sample Time: 1755
Tubing Type: Teflon : **Teflon/Poly** : Poly (circle one)
Final Turbidity (NTUs) : 4.3
Casing Inner Diameter (inches): 2.5
Purge Rate (ml/min) 230
Purge Rate d/sampling (ml/min): 200
Sample Analyses: VOCs (SW8260) Ni (SW6010B) and Total Uranium (ASTM-D5174)
Equipment Serial #:

Time	Purge Volume (L)	pH	Temperature (°C)	Conductivity (µs/cm)	Turbidity (NTUs)	DO (mg/L)	ORP (mV)	Water Level (ft TOIC)	Comments

1745	21.1	7.98	16.01	906	4.3	3.90	50	61.78	

Key:
BGS = Below ground surface.
°C = Degrees centigrade.
DO = Dissolved oxygen.
mg/L = Milligrams per liter
mV = Millivolts.
NTU = Nephelometric turbidity unit.
ORP = Redox potential.
ppm = Parts per million.
PVC = Polyvinyl chloride.
TOIC = Top of inner (PVC) casing.

Key:

BGS = Below ground surface.
°C = Degrees centigrade.
DO = Dissolved oxygen.
mg/L = Milligrams per liter
mV = Millivolts.
NTU = Nephelometric turbidity unit.
ORP = Redox potential.
ppm = Parts per million.
PVC = Polyvinyl chloride.
TOIC = Top of inner (PVC) casing.

Groundwater Sample Log

Site: Sylvania Corning FUSRAP
Well No.: MW33S
Sample Date: 11/16/2012
Sampling Device: Dedicated Bladder Pump
Well Depth (feet TOIC):75
Screen Interval (feet TOIC):65-75
Initial Water Level (Feet TOIC):55.73
Final Water Level (feet TOIC):55.73
Casing Type: **PVC** Steel (circle one)
Personnel: M. Cameron/T. Dillon

Sample ID: MW-33S-R2/MW-515-GW-R2
Purge Start Time:0942
Sample Time: 1020
Final Turbidity (NTUs) : 0
Casing Inner Diameter (inches): 2
Purge Rate (ml/min): 200
Purge Rate d/sampling (ml/min):200
Sample Analyses: VOCs (SW8260) Ni (SW6010B) and Total Uranium (ASTM-D5174)
2x Purge System Volume #: 3.75 L
